    set visibility enable
  next
end
```

To verify that the address range was added correctly:

Go to *Firewall Objects > Address > Groups*. Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall multicast-address
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

## Service Category

Add a new category to the list of Service Categories

You plan on adding a number of devices such as web cameras that will allow the monitoring of the physical security of your datacenter. A number of non-standard services will have to be created and you would like to keep them grouped together under the heading of “Surveillance”

Go to *Firewall Objects > Service > Services* and select *Create New > Category*.

Fill out the fields with the following information

<b>Name</b>	Surveillance
<b>Comments</b>	For DataCenter Surveillance Devices

Select *OK*.

Enter the following CLI command:

```
config firewall service category
    Edit Surveillance
        Set comment "For DataCenter Surveillance Devices"
    end
```

To verify that the category was added correctly:

Go to *Firewall Objects > Service > Services*. Select *Create New > Custom Service*. Go to the *Category* Field and use the drop down menu arrow to open the drop down menu. The new category should be displayed.

Enter the following CLI command:

```
config firewall service category
    show
```

This should bring up all of the categories. Check to see that the new one is displayed.

## TCP/UDP/SCTP Service

To create and configure a TCP/UDP/STCP protocol type service.

You have set up some new web cams at work that send a constant live feed to a security service. Not only do these cameras have a feed that can be sent offsite they can be remotely managed from a browser or an application.

The ports that need to be opened to use all of the features of the web cams are:

- Management by browser - TCP on port 8000
- Real time video feed - UDP on port 4000
- Connection through vendor application - SCTP on port 1600

The IP address of the offsite service is 256.25.56.12 (Not a valid IP address. Used for example only)

- One service will be needed for the incoming connections
- One service will be needed for the outgoing connections

The IT manager would like the service for the outgoing data stream to be tied to the destination of the Surveillance service site so that service can only be used for that one vendor.

### To add the incoming service

Go to *Firewall Objects > Service > Services* and select *Create New > Custom Service*.

Fill out the fields with the following information

<b>Name</b>	WebCam_Connection-incoming
<b>Comments</b>	<Input into this field is optional>
<b>Service Type</b>	Firewall
<b>Color</b>	<Changing this value is optional>
<b>Show in Service List</b>	Check in check box
<b>Category</b>	Surveillance
<b>Protocol Type</b>	TCP/UDP/SCTP
<b>IP/FQDN</b>	<Leave blank>

<b>Protocol</b>	<b>Destination Port</b>		<b>Source Port</b>	
	Low	High	Low	High
<b>TCP</b>	8000	8000	1	65535
<b>SCTP</b>	16000	16000	1	65535

The source port range can be left blank as the default is 1 to 65535.

Select *OK*.

Enter the following CLI command:

```
config firewall service custom
edit WebCam_Connection-incoming
set protocol TCP/UDP/SCTP
set tcp-portrange 8000
set sctp-portrange 16000
set visibility enable
end
```

### To add the outgoing service

Go to *Firewall Objects > Service > Services* and select *Create New > Custom Service*.

Fill out the fields with the following information

<b>Name</b>	WebCam_Connection-outgoing
<b>Comments</b>	<Input into this field is optional>
<b>Service Type</b>	Firewall
<b>Color</b>	<Changing this value is optional>

<b>Show in Service List</b> <input type="checkbox"/> Check in check box				
<b>Category</b>	Surveillance			
<b>Protocol Type</b>	TCP/UDP/SCTP			
<b>IP/FQDN</b>	256.25.56.12			
	<b>Destination Port</b>		<b>Source Port</b>	
<b>Protocol</b>	Low	High	Low	High
<b>TCP</b>	4000	4000	1	65535

Select *OK*.

Enter the following CLI command:

```
config firewall service custom
edit WebCam_Connection-incoming
Set protocol TCP/UDP/SCTP
Set category Surveillance
Set udp-portrange 4000
Set iprange 256.25.56.12
Set visibility enable
end
```

To verify that the category was added correctly:

Go to *Firewall Objects > Service > Services*. Check that the services have been added to the service list and that they are correct.

Enter the following CLI command:

```
config firewall service custom
edit <the name of the service that you wish to verify>
Show full-configuration
```

This should bring up all of the details of the service.

## ICMP Service

The Security Officer would like to block the use of the traceroute utility through the network. The IT manager insists that ping and other ICMP utility must be allows for the task of diagnosing connectivity, so it is agreed that only traceroute functionality will be blocked.

The ICMP type for traceroute is 30. There is no codes with the type.

Web-based Manager Instructions

Go to *Firewall Objects > Service > Services* and select *Create New > Custom Service*.

Fill out the fields with the following information

Field Name	Field Value
<b>Name</b>	traceroute

<b>Comments</b>	<Input into this field is optional>
<b>Service Type</b>	Firewall
<b>Color</b>	<Changing this value is optional>
<b>Show in Service List</b>	Check in check box
<b>Category</b>	Uncategorized
<b>Protocol Type</b>	ICMP
<b>Type</b>	30
<b>Code</b>	<Leave blank>

Select *OK*.

Enter the following CLI command:

```
config firewall service custom
edit traceroute
set protocol ICMP
set icmp-type 30
set visibility enable
end
```

To verify that the category was added correctly:

Go to *Firewall Objects > Service > Services*. Check that the services have been added to the services list and that they are correct.

Enter the following CLI command:

```
config firewall service custom
edit <the name of the service that you wish to verify>
show full-configuration
```

## ICMPv6 Service

The IT Manager is doing some diagnostics and would like to temporarily block the successful replies of ICMP Node information Responses between 2 IPv6 networks.

The ICMP type for ICMP Node informations responses is 140. The codes for a successful response is 0.

Web-based Manager Instructions

Go to *Firewall Objects > Service > Services* and select *Create New > Custom Service*.

Fill out the fields with the following information

Field Name	Field Value
<b>Name</b>	diagnostic-test1
<b>Comments</b>	<Input into this field is optional>
<b>Service Type</b>	Firewall

<b>Color</b>	<Changing this value is optional>
<b>Show in Service List</b>	Check in check box
<b>Category</b>	Uncategorized
<b>Protocol Type</b>	ICMP6
<b>Type</b>	140
<b>Code</b>	0

Select *OK*.

Enter the following CLI command:

```
config firewall service custom
edit diagnostic-test1
set protocol ICMP6
set icmp-type 140
set icmp-code 0
set visibility enable
end
```

To verify that the category was added correctly:

Go to *Firewall Objects > Service > Services*. Check that the services have been added to the services list and that they are correct.

Enter the following CLI command:

```
config firewall service custom
edit <the name of the service that you wish to verify>
show full-configuration
```

## Service Group

The company provide email services for a number of different companies. They have a standard list of services that they like to keep open to their customer's email servers, including webmail services. The company prides itself on getting a customer up and going the same day so they use standard templates for everything to make sure nothing is forgotten including the services that are available.

The services include:

- IMAP
- IMAPS
- POP3
- POP3S
- SMTP
- SMTPS
- HTTP
- HTTPS
- Email\_Admin - a custom service for administration of the servers

Go to Firewall Objects > Service > Groups and select *Create New*.

Fill out the fields with the following information:

Field	Value
Group Name	Cust_Email_Serv_Template
Comments	(Optional)
Color	(Optional)
Type	Firewall
Members	(click to add...choose from the drop down <ul style="list-style-type: none"><li>• IMAP</li><li>• IMAPS</li><li>• POP3</li><li>• POP3S</li><li>• SMTP</li><li>• SMTPS</li><li>• HTTP</li><li>• HTTPS</li><li>• Email_Admin</li></ul> )

Select *OK*.

Enter the following CLI command:

```
config firewall service group
edit Cust_Email_Serv_Template
set member "IMAP" "IMAPS" "POP3" "POP3S" "SMTP" "SMTPS" "HTTP"
"HTTPS" "Email_Admin"
next
end
```

To verify that the category was added correctly:

Go to *Firewall Objects > Service > Groups*. Check that the service group has been added to the services list and that it is correct.

Enter the following CLI command:

```
config firewall service group
edit <the name of the service that you wish to verify>
show full-configuration
```

## Virtual IP address

The company has an web server on the internal network that needs to be accessed from the Internet.

- The internal IP address is 192.168.50.37
- The external IP address is 256.85.94.60 (for example use only. Not a valid IP address)
- The external IP address is assigned by ISP "A" on WAN1
- The port that needs to be mapped is 80

Go to *Firewall Objects > Virtual IP> Virtual IP* and select *Create New*.

Fill out the fields with the following information.

Field	Value
Name	Web1-VIP
Comments	Virtual IP for the Forum Webserver
Color	<optional>
External Interface	wan1
Type	(This field is only changeable in the CLI
Source Address Filter	<leave blank or default setting>
External IP Address/Range	256.85.94.60
Mapped IP Address/Range	192.168.50.37
Port Forward	enabled
Protocol	TCP
External Service Port	80
Map to Port	80

Select *OK*.

Enter the following CLI command:

```
config firewall vip
edit Web1-VIP
    set comment "Virtual IP for the Forum Webserver"
    set extintf wan1
    set extip 256.85.94.60
    set mappedip 192.168.50.37
    set portforward enable
    set protocol tcp
    set extport 80
    set mapped port 80
end
end
```

To verify that the category was added correctly:

Go to *Firewall Objects > Virtual IP> Virtual IP*. Check that the virtual IP address has been added to the list and that it is correct.

Enter the following CLI command:

```
config firewall vip
    edit <the name of the vip that you wish to verify>
        show full-configuration
```

## VIP Group

The company has only a single external IP address but multiple servers with different functions running on its internal LAN that need to be accessed from the Internet.

- The external IP address of the company on wan1 is 256.34.56.149 (for example use only. Not a valid IP address)
- The webserver is on the internal LAN on 192.168.100.86
- The webserver needs to answer on ports 80 443
- The administration of the FortiGate firewall connects on port 4443 instead of 443
- There is are also a separate email server, FTP server, and Terminal Server for specialised applications.
- 2 Virtual IPs have been created to map 256.34.56.149 to 192.168.100.86 on ports 80 and 443. The names are webserver\_80 and webserver\_443 respectively.

Go to *Firewall Objects > Virtual IP> Virtual IP* and select *Create New*.

Fill out the fields with the following information.

Field	Value
Group Name	WebServer_Grp
Comments	(Optional)
Color	(Optional)
Interface	wan1

Move the Following “Available VIPs:” to the “Members” field:

- “webserver\_80”
- “webserver\_443”

Enter the following CLI command:

```
config firewall vipgrp
    edit WebServer_Grp
        set member "webserver_80" "webserver_443"
    next
end
```

To verify that the category was added correctly:

Go to *Firewall Objects > Virtual IP> Group*. Check that the virtual IP address group has been added to the list and that it is correct.

Enter the following CLI command:

```
config firewall vipgrp
edit <the name of the vip that you wish to verify>
show full-configuration
```

## IP Pool

Your company has an application server on the internal network that sends out regular data updates to an offsite service. In order to make the service site more secure, they only accept connections from predefined IP address. If the external IP address of the FortiGate firewall interface were used that would mean that the service would be accepting sessions from just about any user in the network so a separate IP address need so be assigned for the Network Address Translation.

- The external address that will be used is one that has been assigned to the company by the ISP on WAN2
- The address is 256.100.42.129 (for example use only. Not a valid IP address)

*Note:* the ARP interface cannot be set in the Web-based Manager but as this is the only path that the traffic will be coming from the outside this should not be an issue. The setting has been included in the CLI instructions so that you will now how to set it in a situation where you want the ARP replies to be answered only on a specific interface.

Go to *Firewall Objects > Virtual IP > IP Pools*

Fill out the fields with the following information:

Field	Value
Name	App_Server1
Comments	Addresses assignment for this server only.
Type	One-to-One
External IP Range/Subnet2	256.100.42.129
ARP Reply	enabled

Select *OK*

Enter the following CLI command:

```
config firewall ippool
edit App_Server1
set comments 'Addresses assignment for this server only.'
set type one-to-one
set arp-reply enable
set arp-intf wan2
set startip 256.100.42.129
set endip 256.100.42.129
end
```

To verify that the category was added correctly:

Go to *Firewall Objects > Virtual IP > IP Pools*

Check that the IP Pool has been added to the list of IP Pools and that the listed settings are correct.

Enter the following CLI command:

```
config firewall ippool
    edit <the name of the IP Pool you wish to verify>
        show full-configuration
```

## Central NAT Table

The company has a server on the Development LAN that needs to communicate with a server at a remote site over the Internet. One of the restrictions on the communications between these systems is that the IP address and source port must be specific.

- The traffic going out on to the Internet must be NATed
- The traffic is coming from a server with the IP address 192.168.150.86
- An address called “app-server” has been created for the address 192.168.150.86 on the port1 interface
- The external interface must be 256.23.45.67
- An address called "app-server-ext" has been created for the address 256.23.45.67 on the wan1 interface
- The originating traffic from the server originates in the port range from 2000 to 3000
- The remote site requires that the source TCP port must be within the 12000 to 13000 range

The original address and Translated Address fields require values that are address names that are listed in the address section of Firewall Objects.

Go to *Policy > Policy > Central NAT Table*.

Create a new NAT table

Fill out the fields with the following information:

Field	Value
Source Address	app-server
Translated Address	app-server-ext
Original Source Port	2000
Translated Port	12000-13000

Select *OK*

Enter the following CLI command:

```
config firewall central-nat
edit 0
set orig-addr app-server
set nat-ippool app-server-ext
set orig-port 2000
set nat-port 12000-13000
next
end
```

To verify that the table was added correctly:

Go to *Policy > Policy > Central NAT Table*

Check that the table has been added to the list of Central NAT Tables and that the listed settings are correct.

Enter the following CLI command:

```
config firewall central-nat
show full-configuration
```

Verify that the listing of tables includes the one that you have just configured, with the correct settings.

When configuring the Central NAT in the GUI you may notice that only those addresses which have been configured to be associated with *any* interface are displayed in the drop down menu for choosing a Source Address and yet the CLI will allow any address to be used, not just those associated with *any* interface. This is because by default the policies in the GUI use a function of cross referencing which addresses are allowed based on which interface is involved in the policy. When combined with the aspect of Central NAT that doesn't restrict to a specific interface. This means the only addresses will be allowed are those associated with the *any* interface. The CLI does not have this cross referencing function which is why the CLI seems less restrictive. However, more care must be taken when using the CLI to make sure that appropriate addresses are used.

---

## Firewall Schedule - Recurring

The Company wants to allow the use of Facebook by employees, but only during none business hours and the lunch break.

- The business hours are 9:00 p.m. to 6:00 p.m.
- The Lunch break is 12:00 p.m. to 1:00 p.m.
- The plan is to create a schedule to cover the morning business hours and the afternoon business hours and block access to the Facebook web site during that time.

Go to *Firewall Objects > Schedule > IP Recurring*.

Create a new schedule

Fill out the fields with the following information:

Field	Value
Name	Morning_Business_Hours

#### Day of the Week

Sunday	disabled
Monday	enabled
Tuesday	enabled
Wednesday	enabled
Thursday	enabled
Friday	enabled
Saturday	disabled

Start Time: Hour: 09 Minute: 00

Stop Time: Hour: 12 Minute: 00

Select *OK*

Enter the following CLI command:

```
config firewall schedule recurring
edit Morning_Business_Hours
set day monday tuesday wednesday thursday friday
set start 09:00
set end 12:00
end
```

Create a second new schedule.

Field	Value
Name	Afternoon_Business_Hours

#### Day of the Week

Sunday	disabled
Monday	enabled
Tuesday	enabled
Wednesday	enabled
Thursday	enabled

Field	Value
Friday	enabled
Saturday	disabled

Start Time:	Hour:	13	Minute:	00
Stop Time:	Hour:	18	Minute:	00

Select *OK*

Enter the following CLI command:

```
config firewall schedule recurring
edit Afternoon_Business_Hours
set day monday tuesday wednesday thursday friday
set start 13:00
set end 18:00
end
```

To verify that the schedule was added correctly:

Go to *Firewall Objects > Schedule > Recurring*

Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

Enter the following CLI command:

```
config firewall schedule recurring
edit <the name of the schedule you wish to verify>
show full-configuration
```

## Firewall Schedule - One-time

The company wants to change over their web site image to reference the new year. They have decided to take this opportunity to do some hardware upgrades as well. Their web site is business oriented so they have determined that over New Year's Eve there will be very limited traffic.

- They are going to need a maintenance window of 2 hours bracketing midnight on New Year's Eve.

Go to *Firewall Objects > Schedule > One-time*.

Create a new schedule

Fill out the fields with the following information:

	Year	Month	Day	Hour	Minute
Start	2012	12	31	23	00
Stop	2013	1	1	1	00

Select *OK*

Enter the following CLI command:

```
config firewall schedule onetime
edit maintenance_window
set start 23:00 2012/12/31
set end 01:00 2013/01/01
next
end
```

To verify that the schedule was added correctly:

Go to *Firewall Objects > Schedule > One-time*

Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

Enter the following CLI command:

```
config firewall schedule onetime
edit <the name of the schedule you wish to verify>
show full-configuration
```

## Schedule Group

In order to make the administration of the policies easier a group needs to be created.

Go to *Firewall Objects > Schedule > Groups*.

Create a new group

Fill out the fields with the following information:

Field	Value
Group Name	Business_Hours
Available Schedules	Morning_Business_Hours Afternoon_Business_Hours

Use arrows to move schedules from the “Members” field to the “Available Schedules:” field

Select *OK*

Enter the following CLI command:

```
config firewall service group
edit Business_Hours
set member Morning_Business_Hours Afternoon_Business _ours
end
```

To verify that the schedule was added correctly:

Go to *Firewall Objects > Schedule > Groups*

Check that the schedule group with the name you used has been added to the list of schedule groups.

Enter the following CLI command:

```
config firewall service group
edit <the name of the schedule group you wish to verify>
show full-configuration
```

## Proxy Option

The company will be using a number of the Security Profiles features on various policies but wants to use as few profiles as possible to make administration simpler. The decision has been made to have two profiles, the default one and a single customized one that will be a combination of the settings required to cover the situations that will not be covered by the default profile.

The company profile will have the following parameters:

- There are no FTP servers running on the site so there is no need for FTP.
- The company will use the Fortinet supplied default certificate called "Fortinet\_CA\_SSLProxy"
- The company will only be doing inspecting of SSL over HTTP, SMTP and IMAP.
- The company has a non-standard IMAP implementation the uses ports 1143 and 1993 for IMAP and IMAPS respectively.
- Deep Scanning is to be enabled on any SSL traffic regardless of port and the traffic logged but nothing is blocked.
- The Comfort Clients is to be used with a ratio of 1 byte for every 15 seconds.
- There is a lot of varied email traffic so there is to be no blocking of emails due to size beyond the settings on the mail servers.
- The Security Officer insists that invalid SSL certificates not be allowed.

Go to Policy > Policy > Proxy Options

Create a new profile

Fill out the fields with the following information:

Field	Value
Name	example_standard
Comments	<optional>

### Protocol Port Mapping:

Enable	Protocol	Inspection Ports
enabled	HTTP	Specify and <leave on default setting.>
enabled	SMTP	Specify and <leave on default setting.>
enabled	POP3	Specify and <leave on default setting.>
enabled	IMAP	Specify and 1143
not enabled	FTP	
enabled	NNTP	Specify and <leave on default setting.>

Enable	Protocol	Inspection Ports
enabled	MAPI	<leave on default setting.>
enabled	DNS	<leave on default setting.>

### SSL Inspection Options

CA Certificate: "Fortinet\_CA\_SSLProxy" from drop down menu

Inspect All Ports: Not enabled

Enable	Protocol	Inspection Port(s)
enabled	HTTPS	<leave as default>
enabled	SMTPS	<leave as default>
enabled	POP3S	<leave as default>
enabled	IMAPS	1993
	FTPS	

### SSH Inspection Options

Enable SSH Deep Scan: enabled

Protocol	Inspection Ports
SSH	Any
Exec	Block: not enabled   Log: enabled
Port-Forward	Block: not enabled   Log: enabled
SSH-Shell	Block: not enabled   Log: enabled
x11-Filter	Block: not enabled   Log: enabled

### Common Options

Field	Value
Comfort Clients	enabled
• Interval (Seconds)	15
• Amount(bytes)	1
Block Oversized File/Email	not enabled
• Threshold(MB)	not enabled
Allow Invalid SSL Certificates	not enabled

### Web Options

Field	Value
Enabled Chunked Bypass	not enabled
Add Fortinet Bar	not enabled
• Communication Port	<leave as default>

### Email Options

Field	Value
Allow Fragmented Messages	not enabled
Append Signature (SMTP)	not enabled
Email Signature Text	not enabled

Select *OK*

Enter the following CLI command:

```
config firewall profile-protocol-options
edit example_standard
config http
set options clientcomfort no-content-summary
set comfort-interval 15
next
config https
set status enable
set options clientcomfort no-content-summary
set comfort-interval 15
next
config ftp
set status disable
set options clientcomfort no-content-summary splice
set comfort-interval 15
next
config ftps
set options clientcomfort no-content-summary splice
set comfort-interval 15
next
config imap
set ports "1143"
set options fragmail no-content-summary
next
config imaps
set ports "1993"
set status enable
set options fragmail no-content-summary
next
config mapi
set options fragmail no-content-summary
next
config pop3
set options fragmail no-content-summary
next
config pop3s
set status enable
set options fragmail no-content-summary
next
config smtp
set options fragmail no-content-summary splice
next
config smtps
set status enable
set options fragmail no-content-summary splice
next
```

```

config nntp
    set options no-content-summary splice
    next
config ssh
    set inspect-all enable
    set log x11-filter ssh-shell exec port-forward
    next
end

```

## Oversized Files

A couple of variations on the example could have to do with the processing of oversized files at a level other than the default setting. The ways that it can be approached are:

1. Set a non default threshold size and block the files
2. Set a non default threshold size and not scan the files over the threshold but allow them to pass through the FortiGate firewall.

In the following instructions:

- We will just use 2 MB as the new threshold.
- In the CLI instructions we will limit the configuration to just the HTTP settings for the purposes of brevity and simplicity.

### Option 1

Option 1 can be done in the GUI.

Go to Policy > Policy > Proxy Options

Create a new profile

Fill out the fields with the following information:

#### Common Options

Field	Value
Comfort Clients	enabled
• Interval (Seconds)	15
• Amount(bytes)	1
Block Oversized File/Email	enabled
• Threshold(MB)	2
Allow Invalid SSL Certificates	not enabled

Select *OK*

Enter the following CLI command:

```

config firewall profile-protocol-options
  edit example_standard
    config http
      set options clientcomfort no-content-summary oversize
      set oversize-limit 2
      set comfort-interval 15
    next
  end

```

## Option 2

Option 2 can only be done in the CLI.

Enter the following CLI command:

```

config firewall profile-protocol-options
  edit example_standard
    config http
      set options clientcomfort no-content-summary
      set oversize-limit 2
      set comfort-interval 15
    next
  end

```

## Firewall Address Policy

A policy must be created to all traffic from one of the subnets off of the FortiGate out to the Internet.

- The traffic needs to be NATed
- The Internal subnet that needs to be connected is connected to port 1
- The subnet is from 192.168.1.1 to 192.168.1.255
- There is a user defined address for this subnet named “lan\_192.168.1.x”
- The policy is for general Internet access over wan1.
- The IT manager would like to keep an eye on the kinds of sites that users are going to so for the time being even allowed traffic will be logged.
- To prevent the spread of malware even the outgoing traffic will be screened for viruses using the “basic\_outgoing\_av” profile that has already been defined by the IT Manager.
- There is no schedule restriction on access to the Internet so the schedule is the predefined “always”.
- There is no restrictions yet on what protocols are allowed so the predefines services should be used.
- In order to prevent any HR issues a webfilter has been defined by the IT manager that blocks access to inappropriate sites. The profile is called “basic\_web\_filter”

Go to *Policy > Policy > Policy*.

Create a new policy

Fill out the fields with the following information:

Field	Value
Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	lan_192.168.1.x
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	Accept
Enable NAT	enable
Use Destination Interface Address	enable
Log Allowed Traffic	enable
Enable WebCache	not enabled
Enable WAN Optimization	not enabled
Traffic Shaping	enabled

### Security Profiles

Security Profiles	Status	Profile Name
AntiVirus	ON	basic_outgoing_av
Web Filter	ON	basic_web_filter
Application Control	OFF	(option should be greyed out)
IPS	OFF	(option should be greyed out)
Email Filter	OFF	(option should be greyed out)
DLP Sensor	OFF	(option should be greyed out)
VoIP	OFF	(option should be greyed out)
ICAP	OFF	(option should be greyed out)

Select OK

Enter the following CLI command:

```
config firewall policy
edit 0
    set srcintf port1
    set dstintf wan1

end
```

## Firewall User Identity Policy

There is a Server on the Internal LAN that is used as a resource by sales people that are out on the road and at home. The sales people and their administrator are the only ones that are allowed access to the server "SalesServer". Because of the importance of the data on the server it needs to be backed up on a regular bases and to make sure that all of the files are available for backup no one is allowed access during the scheduled backup time.

- Firewall User Group has been created: "sales". This is a group defined for more than one purpose.
- Firewall User has been created: "jsmith", who is the administrator. "jsmith" is not a member of the sales group and can't be placed in it because of other resources that the group has access to.
- A Virtual IP has been defined for the server "SalesServer" mapped from an external address to an internal address on port9. Port forwarding is enabled on TCP port 443 for the application that the sales people use.
- The schedule "Non-Maintenance\_Window" has been created (between 2 a.m. and 3 a.m.) by starting the window at 3:00 and stopping at 2:00 (If the stop time is set earlier than the start time, the stop time will be during the next day).
- Because there is access from the Internet to the internal network the company's HTTPS Server IPS profile, called "Protect\_HTTPS\_Server" will be enabled.

Go to *Policy > Policy > Policy*.

Create a new policy

Fill out the fields with the following information:

Field	Value
Policy Type	Firewall
Policy Subtype	User Identity

Field	Value
Incoming Interface	wan1
Source Address	all
Outgoing Interface	port9
Enable NAT	not enabled
Enable Web cache	not enabled
Enable WAN Optimization	not enabled
Certificate	No Certificate
Firewall	enabled
Fortinet Single Sign-On	not enabled
WiFi Single Sign-on	not enabled
NTLM Authentications	not enabled
Customize Authentication Messages	(optional)
Add tag	(optional)
Comments	(optional)

In the Configure Authentication Rules section, create a new Authentication rule by filling out the fields with the following information.

Field	Value
Destination Address	SalesServer (virtual IP address)
Group(s)	sales
User(s)	jsmith
Schedule	Non-Maintenance_Window
Service	HTTPS
Action	(automatically assigned value of "ACCEPT")
Log Allowed Traffic	(optional)
Traffic Shaping	(optional)

In the Security Profiles Section:

Enable and select the security profiles as follows:

Security Profiles	Status	Profile Name
AntiVirus	OFF	(option should be greyed out)
Web Filter	OFF	(option should be greyed out)
Application Control	OFF	(option should be greyed out)
IPS	ON	Protect_HTTPS_Server
Email Filter	OFF	(option should be greyed out)
DLP Sensor	OFF	(option should be greyed out)
VoIP	OFF	(option should be greyed out)
ICAP	OFF	(option should be greyed out)

Select *OK*

Enter the following CLI command:

```
config firewall policy
  edit 0
    set srcintf "wan1"
    set dstintf "port9"
    set srcaddr "all"
    set action accept
    set identity-based enable
    config identity-based-policy
      edit 1
        set schedule "Non-Maintenance_Window"
        set utm-status enable
        set profile-type single
        set groups "sales"
        set users "jsmith"
        set dstaddr "SalesServer"
        set service "HTTPS"
        set ips-sensor "Protect_HTTPS_Server"
      next
    end
```

## Firewall Device Identity Policy

The company is instituting a BYOD pilot project. They are going to be letting employee's personal devices connect through a wireless network. Most will only be allowed only to the Internet but some will have access to the Internal LAN.

- The wireless interface the users will be connecting on is "WiFi".
- The source address has been defined as the DHCP scope assigned to the wireless network, "Internal\_wireless".
- The Internal Network is on the interface designated as "LAN"
- There is no need to NAT the traffic.
- The AntiVirus Profile to be used is "Internal-AV", already defined.
- The Application Profile to be used is "Internal-AC", already defined.
- The IPS Profile to be used is "Internal-IPS", already defined.
- The Device group for this policy is "IT\_Personnel\_phones".
- The IT team is a trusted group that will be accessing practically everything so the schedule will be the predefined "always" and the Service will be the predefined "ALL".
- While the IT team is trusted the company would like to verify that they are compliant with the Endpoint profile so the check for this must be enabled on the policy.

Go to *Policy > Policy > Policy*.

Create a new policy

Fill out the fields with the following information:

Field	Value
Policy Type	Firewall
Policy Subtype	Device Identity
Incoming Interface	wifi
Source Address	all
Outgoing Interface	port9
Enable NAT	not enabled
Customize Authentication Messages	(optional)
Add tag	(optional)
Comments	(optional)

In the Configure Authentication Rules section, create a new Authentication rule by filling out the fields with the following information.

Field	Value
Destination Address	Internal_Network
Device	IT_Personnel_Phones
Compliant with Endpoint Profile	enable
Schedule	always
Service	ALL
Action	(automatically assigned value of "ACCEPT")
Log Allowed Traffic	(optional)
Traffic Shaping	(optional)

In the Security Profile Section:

Enable and select the security profiles as follows:

Security Profiles	Status	Profile Name
AntiVirus	ON	Internal-AV
Web Filter	OFF	(option should be greyed out)
Application Control	ON	Internal-AC
IPS	ON	Internal-IPS
Email Filter	OFF	(option should be greyed out)
DLP Sensor	OFF	(option should be greyed out)
VoIP	OFF	(option should be greyed out)
ICAP	OFF	(option should be greyed out)

Select *OK*

Enter the following CLI command:

```
config firewall policy
edit 0
    set srcintf "wifi"
    set dstintf "LAN"
    set srcaddr "Internal_wireless"
    set action accept
    set identity-based enable
    set identity-from device
    config identity-based-policy
    edit 1
        set schedule always
        set utm-status enable
        set dstaddr Internal_Network
        set service ALL
        set devices IT_Personnel_phones
        set endpoint-compliance enable
        set av-profile Internal-AV
        set ips-sensor Internal-IPS
        set application-list Internal-AC
    next
end
```

## DoS Policy

The company wishes to protect against Denial of Service attack. They have chosen some where they wish to block the attacks of the incidence goes above a certain threshold and for some others they are just trying to get a baseline of activity for those types of attacks so they are letting the traffic pass through without action.

- The interface to the Internet is on WAN1
- There is no requirement to specify which addresses are being protected or protected from.
- The protection is to extend to all services.
- The TCP attacks are to be blocked
- The UDP, ICMP, and IP attacks are to be recorded but not blocked.
- The tcp\_syn\_flood attack's threshold is to be changed from the default to 1000

Go to *Policy > Policy > DoS Policy*.

Create a new policy

Fill out the fields with the following information:

Field	Value
Incoming Interface	wan1
Source Address	all

Field	Value
Destination Addresses	all
Service	ALL

#### Anomalies

Name	Status	Logging	Action	Threshold
tcp_syn_flood	enabled	enabled	Block	1000
tcp_port_scan	enabled	enabled	Block	<default value>
tcp_src_session	enabled	enabled	Block	<default value>
tcp_dst_session	enabled	enabled	Block	<default value>
udp_flood	enabled	enabled	Pass	<default value>
udp_scan	enabled	enabled	Pass	<default value>

end
```

# Multicast forwarding

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on.

Also RIPv2 uses multicasting to share routing table information, OSPF uses multicasting to send hello packets and routing updates, Enhanced Interior Gateway Routing Protocol (EIGRP) uses multicasting to send routing information to all EIGRP routers on a network segment and the Bonjour network service uses multicasting for DNS.

A FortiGate unit can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGate units support PIM sparse mode (RFC 4601) and PIM dense mode (RFC 3973) and can service multicast servers or receivers on the network segment to which a FortiGate unit interface is connected. Multicast routing is not supported in transparent mode (TP mode).

To support PIM communications, the sending/receiving applications and all connecting PIM routers in between must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, either sparse mode or dense mode must be enabled on the PIM-router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. In addition, if a FortiGate unit is located between a source and a PIM router, two PIM routers, or is connected directly to a receiver, you must create a security policy manually to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

---

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one Boot Strap Router (BSR), and if sparse mode is enabled, a number of Rendezvous Points (RPs) and Designated Routers (DRs). When PIM is enabled on a FortiGate unit, the FortiGate unit can perform any of these functions at any time as configured.

## Sparse mode

Initially, all candidate BSRs in a PIM domain exchange bootstrap messages to select one BSR to which each RP sends the multicast address or addresses of the multicast group(s) that it can service. The selected BSR chooses one RP per multicast group and makes this information available to all of the PIM routers in the domain through bootstrap messages. PIM routers use the information to build packet distribution trees, which map each multicast group to a specific RP. Packet distribution trees may also contain information about the sources and receivers associated with particular multicast groups.

When a FortiGate unit interface is configured as a multicast interface, sparse mode is enabled on it by default to ensure that distribution trees are not built unless at least one downstream receiver requests multicast traffic from a specific source. If the sources of multicast traffic and their receivers are close to each other and the PIM domain contains a dense population of active receivers, you may choose to enable dense mode throughout the PIM domain instead.

---

An RP represents the root of a non-source-specific distribution tree to a multicast group. By joining and pruning the information contained in distribution trees, a single stream of multicast

packets (for example, a video feed) originating from the source can be forwarded to a certain RP to reach a multicast destination.

Each PIM router maintains a Multicast Routing Information Base (MRIB) that determines to which neighboring PIM router join and prune messages are sent. An MRIB contains reverse-path information that reveals the path of a multicast packet from its source to the PIM router that maintains the MRIB.

To send multicast traffic, a server application sends IP traffic to a multicast group address. The locally elected DR registers the sender with the RP that is associated with the target multicast group. The RP uses its MRIB to forward a single stream of IP packets from the source to the members of the multicast group. The IP packets are replicated only when necessary to distribute the data to branches of the RP's distribution tree.

To receive multicast traffic, a client application can use Internet Group Management Protocol (IGMP) version 1 (RFC 1112), 2 (RFC 2236), or 3 (RFC 3376) control messages to request the traffic for a particular multicast group. The locally elected DR receives the request and adds the host to the multicast group that is associated with the connected network segment by sending a join message towards the RP for the group. Afterward, the DR queries the hosts on the connected network segment continually to determine whether the hosts are active. When the DR no longer receives confirmation that at least one member of the multicast group is still active, the DR sends a prune message towards the RP for the group.

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601: Protocol Independent Multicast - Sparse Mode (PIM-SM). You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
    set multicast-routing {enable | disable}
    config interface
        edit <interface-name>
            set hello-interval <1-65535 seconds>
            set hello-holdtime <1-65535 seconds>
        end
    config pim-sm-global
        config rp-address
            edit <index>
                set ipv6-address <ipv6-address>
            end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

## Dense mode

The packet organization used in sparse mode is also used in dense mode. When a multicast source begins to send IP traffic and dense mode is enabled, the closest PIM router registers the IP traffic from the multicast source (S) and forwards multicast packets to the multicast group address (G). All PIM routers initially broadcast the multicast packets throughout the PIM domain to ensure that all receivers that have requested traffic for multicast group address G can access the information if needed.

To forward multicast packets to specific destinations afterward, the PIM routers build distribution trees based on the information in multicast packets. Upstream PIM routers depend

on prune/graft messages from downstream PIM routers to determine if receivers are actually present on directly connected network segments. The PIM routers exchange state refresh messages to update their distribution trees. FortiGate units store this state information in a Tree Information Base (TIB), which is used to build a multicast forwarding table. The information in the multicast forwarding table determines whether packets are forwarded downstream. The forwarding table is updated whenever the TIB is modified.

PIM routers receive data streams every few minutes and update their forwarding tables using the source (S) and multicast group (G) information in the data stream. Superfluous multicast traffic is stopped by PIM routers that do not have downstream receivers—PIM routers that do not manage multicast groups send prune messages to the upstream PIM routers. When a receiver requests traffic for multicast address G, the closest PIM router sends a graft message upstream to begin receiving multicast packets.

FortiGate units operating in NAT mode can also be configured as multicast routers. You can configure a FortiGate unit to be a Protocol Independent Multicast (PIM) router operating in Sparse Mode (SM) or Dense Mode (DM).

## Multicast IP addresses

Multicast uses the Class D address space. The 224.0.0.0 to 239.255.255.255 IP address range is reserved for multicast groups. The multicast address range applies to multicast groups, not to the originators of multicast packets. [Table 53](#) lists reserved multicast address ranges and describes what they are reserved for:

**Table 53:** Reserved Multicast address ranges

Reserved Address Range	Use	Notes
224.0.0.0 to 224.0.0.255	Used for network protocols on local networks. For more information, see RFC 1700.	In this range, packets are not forwarded by the router but remain on the local network. They have a Time to Live (TTL) of 1. These addresses are used for communicating routing information.
224.0.1.0 to 238.255.255.255	Global addresses used for multicasting data between organizations and across the Internet. For more information, see RFC 1700.	Some of these addresses are reserved, for example, 224.0.1.1 is used for Network Time Protocol (NTP).
239.0.0.0 to 239.255.255.255	Limited scope addresses used for local groups and organizations. For more information, see RFC 2365.	Routers are configured with filters to prevent multicasts to these addresses from leaving the local system.

Creating multicast security policies requires multicast firewall addresses. You can add multicast firewall addresses by going to *Firewall Objects > Address > Addresses* and selecting *Create New > Multicast Address*. The factory default configuration includes multicast addresses for Bonjour(224.0.0.251-224.0.0.251), EIGRP (224.0.0.10-224.0.0.100), OSPF (224.0.0.5-224.0.0.60), all\_hosts (224.0.0.1-224.0.0.1), and all\_routers (224.0.0.2-224.0.0.2).

## PIM Support

A FortiGate unit can be configured to support PIM by going to *Router > Dynamic > Multicast* and enabling multicast routing. You can also enable multicast routing using the `config router multicast` CLI command. When PIM is enabled, the FortiGate unit allocates memory to manage mapping information. The FortiGate unit communicates with neighboring PIM routers to acquire mapping information and if required, processes the multicast traffic associated with specific multicast groups.

The end-user multicast client-server applications must be installed and configured to initiate Internet connections and handle broadband content such as audio/video information.

Client applications send multicast data by registering IP traffic with a PIM-enabled router. An end-user could type in a class D multicast group address, an alias for the multicast group address, or a call-conference number to initiate the session.

Rather than sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use the one multicast group address to forward multicast packets to multiple destinations. Because one destination address is used, a single stream of data can be sent. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them — end-users may use phone books, a menu of ongoing or future sessions, or some other method through a user interface to select the address of interest.

A class D address in the 224.0.0.0 to 239.255.255.255 range may be used as a multicast group address, subject to the rules assigned by the Internet Assigned Numbers Authority (IANA). All class D addresses must be assigned in advance. Because there is no way to determine in advance if a certain multicast group address is in use, collisions may occur (to resolve this problem, end-users may switch to a different multicast address).

### To configure a PIM domain

1. If you will be using sparse mode, determine appropriate paths for multicast packets.
2. Make a note of the interfaces that will be PIM-enabled. These interfaces may run a unicast routing protocol.
3. If you will be using sparse mode and want multicast packets to be handled by specific (static) RPs, record the IP addresses of the PIM-enabled interfaces on those RPs.
4. Enable PIM version 2 on all participating routers between the source and receivers. On FortiGate units, use the `config router multicast` command to set global operating parameters.
5. Configure the PIM routers that have good connections throughout the PIM domain to be candidate BSRs.
6. If sparse mode is enabled, configure one or more of the PIM routers to be candidate RPs.
7. If required, adjust the default settings of PIM-enabled interface(s).

## Multicast forwarding and FortiGate units

In both transparent mode and NAT mode you can configure FortiGate units to forward multicast traffic.

For a FortiGate unit to forward multicast traffic you must add FortiGate multicast security policies. Basic multicast security policies accept any multicast packets at one FortiGate

interface and forward the packets out another FortiGate interface. You can also use multicast security policies to be selective about the multicast traffic that is accepted based on source and destination address, and to perform NAT on multicast packets.

In the example shown in [Figure 176](#), a multicast source on the Marketing network with IP address 192.168.5.18 sends multicast packets to the members of network 239.168.4.0. At the FortiGate unit, the source IP address for multicast packets originating from workstation 192.168.5.18 is translated to 192.168.18.10. In this example, the FortiGate unit is not acting as a multicast router.

## Multicast forwarding and RIPv2

RIPv2 uses multicast to share routing table information. If your FortiGate unit is installed on a network that includes RIPv2 routers, you must configure the FortiGate unit to forward multicast packets so that RIPv2 devices can share routing data through the FortiGate unit. No special FortiGate configuration is required to share RIPv2 data, you can simply use the information in the following sections to configure the FortiGate unit to forward multicast packets.

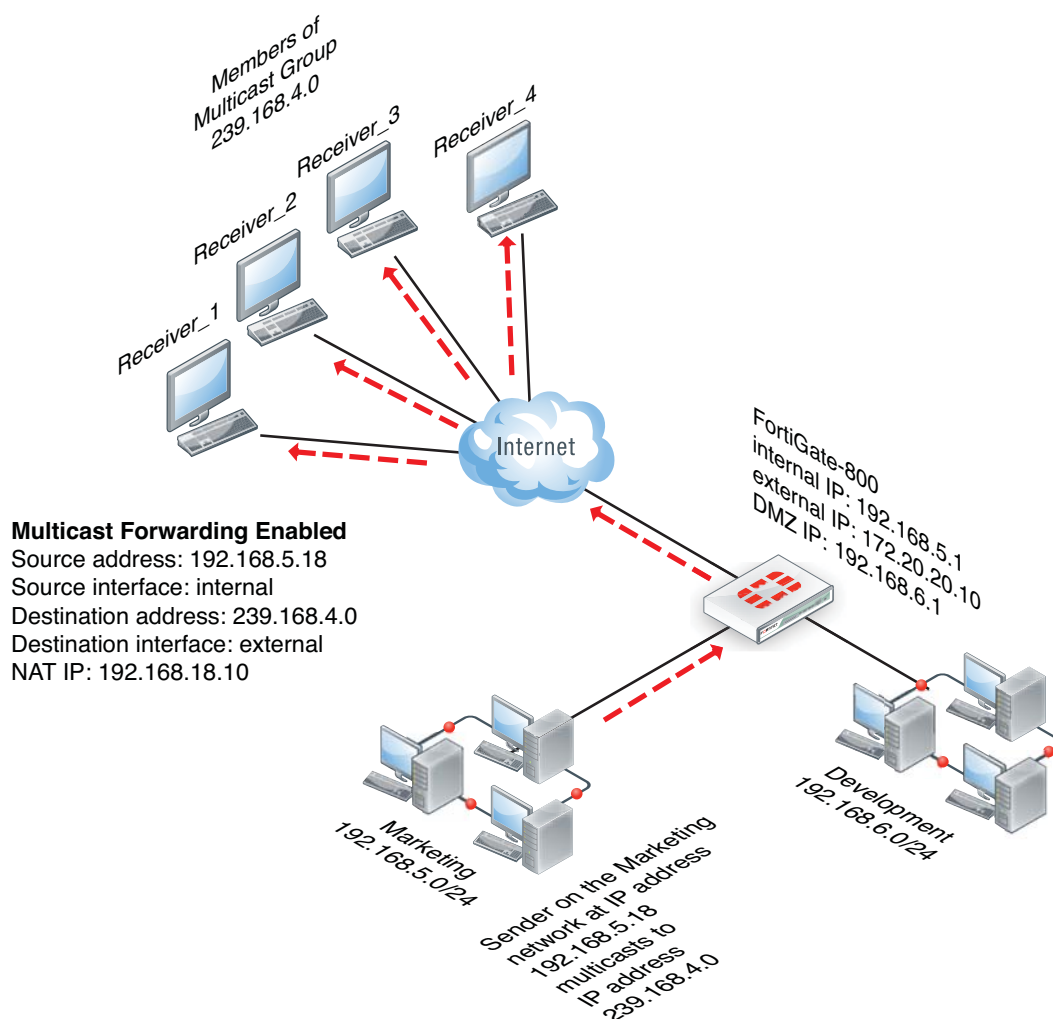

RIPv1 uses broadcasting to share routing table information. To allow RIPv1 packets through a FortiGate unit you can add standard security policies. Security policies to accept RIPv1 packets can use the ANY predefined firewall service or the RIP predefined firewall service.

---

**Figure 176:**Example multicast network including a FortiGate unit that forwards multicast packets

## Configuring FortiGate multicast forwarding

You configure FortiGate multicast forwarding from the Command Line Interface (CLI). Two steps are required:

- [Adding multicast security policies](#)
- [Enabling multicast forwarding](#)

This second step is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

There is sometimes a confusion between the terms “forwarding” and “routing”. These two functions should not be taking place at the same time.

It is mentioned that multicast-forward should be enabled when the FortiGate unit is in NAT mode and that this will forward any multicast packet to all interfaces. However, this parameter should **NOT** be enabled when the FortiGate unit operates as a multicast router (i.e. with a routing protocol enabled). It should only be enabled when there is no routing protocols activated.

## Adding multicast security policies

You need to add security policies to allow packets to pass from one interface to another. Multicast packets require multicast security policies. You add multicast security policies from the CLI using the `config firewall multicast-policy` command. As with unicast security policies, you specify the source and destination interfaces and optionally the allowed address ranges for the source and destination addresses of the packets.

You can also use multicast security policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast security policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- Source and Destination interfaces are optional. If left blank, then the multicast will be forwarded to ALL interfaces.
- Source and Destination addresses are optional. If left un set, then it will mean ALL addresses.
- The `nat` keyword is optional. Use it when source address translation is needed.

## Enabling multicast forwarding

Multicast forwarding is enabled by default. In NAT mode you must use the `multicast-forward` keyword of the `system settings` CLI command to enable or disable multicast forwarding. When `multicast-forward` is enabled, the FortiGate unit forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add security policies to actually allow multicast packets through the FortiGate. In our example, the security policy allows multicast packets received by the internal interface to exit to the external interface.

Enabling multicast forwarding is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

---

Enter the following CLI command to enable multicast forwarding:

```
config system settings
    set multicast-forward enable
end
```

If multicast forwarding is disabled and the FortiGate unit drops packets that have multicast source or destination addresses.

You can also use the `multicast-ttl-notchange` keyword of the `system settings` command so that the FortiGate unit does not increase the TTL value for forwarded multicast packets. You should use this option only if packets are expiring before reaching the multicast router.

```
config system settings
    set multicast-ttl-notchange enable
end
```

In transparent mode, the FortiGate unit does not forward frames with multicast destination addresses. Multicast traffic such as the one used by routing protocols or streaming media may need to traverse the FortiGate unit, and should not be interfere with the communication. To

avoid any issues during transmission, you can set up multicast security policies. These types of security policies can only be enabled using the CLI.

The CLI parameter `multicast-skip-policy` must be disabled when using multicast security policies. To disable enter the command

```
config system settings
    set multicast-skip-policy disable
end
```

In this simple example, no check is performed on the source or destination interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

#### To enable the multicast policy

```
config firewall multicast-policy
    edit 1
        set action accept
    end
```

In this example, the multicast policy only applies to the source port of WAN1 and the destination port of Internal.

#### To enable the restrictive multicast policy

```
config firewall multicast-policy
    edit 1
        set srcintf wan1
        set dstintf internal
        set action accept
    end
```

In this example, packets are allowed to flow from WAN1 to Internal, and sourced by the address 172.20.120.129. This address needs to be configured as an address object. For simplicity we will assume that this address is represented by the address object "example-addr\_A".

#### To enable the restrictive multicast policy

```
config firewall multicast-policy
    edit 1
        set srcintf wan1
        set srcaddr example-addr_A
        set dstintf internal
        set action accept
    end
```

This example shows how to configure the multicast security policy required for the configuration shown. This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18, which will be represented by the address object "example-addr\_X", to destination address range 239.168.4.0, which will be represented by the address object "example-addr\_Y". The policy allows the multicast packets to enter the internal interface and then exit the external

interface. When the packets leave the external interface their source address is translated to 192.168.18.10.

```
config firewall multicast-policy
edit 5
    set srcaddr example-addr_X
    set srcintf internal
    set destaddr example-addr_Y
    set dstintf external
    set nat 192.168.18.10
end
```

This example shows how to configure a multicast security policy so that the FortiGate unit forwards multicast packets from a multicast Server with an IP 10.10.10.10, represented by address object "example-addr\_C", is broadcasting to address 225.1.1.1, represented by address object "example-addr\_D". This Server is on the network connected to the FortiGate DMZ interface.

```
config firewall multicast-policy
edit 1
    set srcintf DMZ
    set srcaddr example-addr_C
    set dstintf Internal
    set dstaddr example-addr_D
    set action accept
edit 2
    set action deny
end
```

## Multicast routing examples

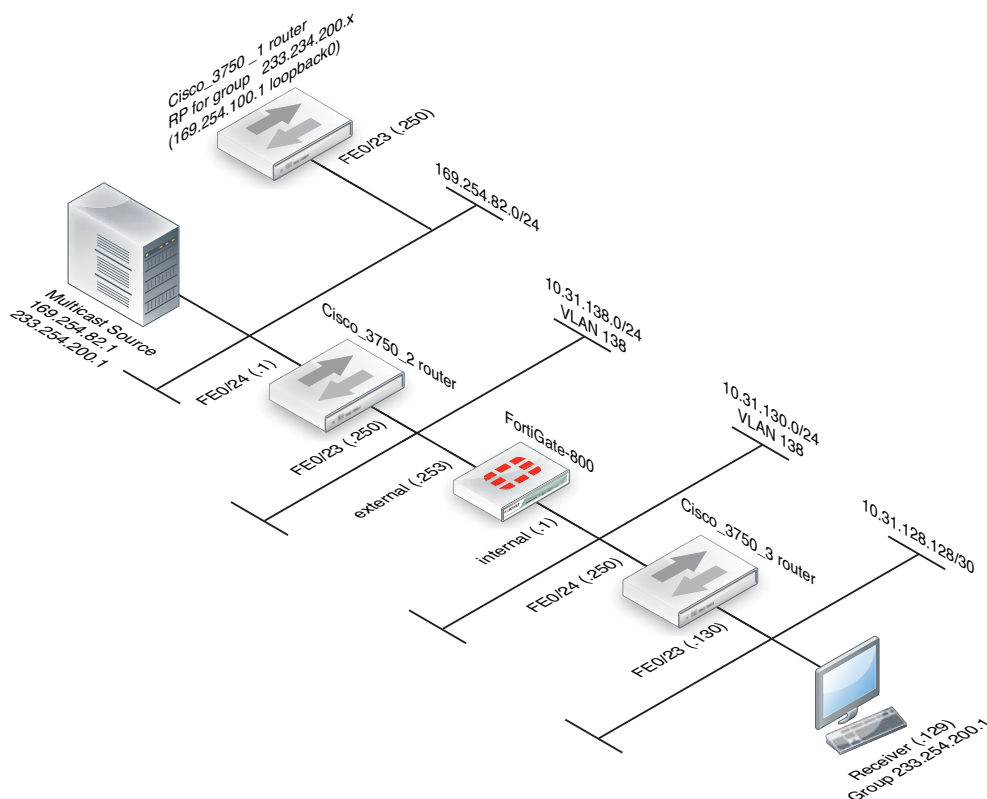

This section contains the following multicast routing configuration examples and information:

- [Example FortiGate PIM-SM configuration using a static RP](#)
- [FortiGate PIM-SM debugging examples](#)
- [Example multicast destination NAT \(DNAT\) configuration](#)
- [Example PIM configuration that uses BSR to find the RP](#)

### Example FortiGate PIM-SM configuration using a static RP

The example Protocol Independent Multicast Sparse Mode (PIM-SM) configuration shown in [Figure 177](#) has been tested for multicast interoperability using PIM-SM between Cisco 3750 switches running 12.2 and a FortiGate-800 running FortiOS v3.0 MR5 patch 1. In this configuration, the receiver receives the multicast stream when it joins the group 233.254.200.1.

**Figure 177:**Example FortiGate PIM-SM topology

The configuration uses a statically configured rendezvous point (RP) which resides on the Cisco\_3750\_1. Using a bootstrap router (BSR) was not tested in this example. See [“Example PIM configuration that uses BSR to find the RP”](#) on page 1055 for an example that uses a BSR.

### Configuration steps

The following procedures show how to configure the multicast configuration settings for the devices in the example configuration.

- [Cisco\\_3750\\_1 router configuration](#)
- [Cisco\\_3750\\_2 router configuration](#)
- [To configure the FortiGate-800 unit](#)
- [Cisco\\_3750\\_3 router configuration](#)

```

## To configure the FortiGate-800 unit

### 1. Configure the internal and external interfaces.

- Internal

Go to *System > Network > Interfaces*.

Select the internal interface

Verify the following settings:

<b>Type:</b>	Physical Interface
<b>Addressing mode:</b>	Manual
<b>IP/Network Mask:</b>	10.31.138.253 255.255.255.0
<b>Administrative Access:</b>	PING

Select *OK*

- External

Go to *System > Network > Interfaces*.

Select the external interface

Verify the following settings:

<b>Type:</b>	Physical Interface
<b>Addressing mode:</b>	Manual
<b>IP/Network Mask:</b>	10.31.130.253 255.255.255.0
<b>Administrative Access:</b>	HTTPS and PING

Select *OK*.

2. Add a firewall addresses.

Go to *Firewall Objects > Address > Addresses*.

- RP

Select *Create New*.

Use the following settings:

<b>Category:</b>	Address
<b>Name:</b>	RP
<b>Type:</b>	Subnet
<b>Subnet/IP Range:</b>	169.254.100.1/32
<b>Interface:</b>	Any

Select *OK*.

- Multicast source subnet

Select *Create New*.

Use the following settings:

<b>Category:</b>	Address
<b>Name:</b>	multicast_source_subnet
<b>Type:</b>	Subnet
<b>Subnet/IP Range:</b>	169.254.82.0/24
<b>Interface:</b>	Any

Select *OK*.

3. Add destination multicast address

Go to *Firewall Objects > Address > Addresses*.

Select *Create New*.

Use the following settings:

<b>Category:</b>	Multicast Address
<b>Name:</b>	Multicast_stream
<b>Type:</b>	Broadcast Subnet
<b>Broadcast Subnet:</b>	233.254.200.0/24
<b>Interface:</b>	Any

Select *OK*.

4. Add standard security policies to allow traffic to reach the RP.

Go to Policy > Policy > Policy

- 1st policy

Select *Create New*

Use the following settings:

<b>Policy Type:</b>	Firewall
<b>Policy Subtype:</b>	Address
<b>Incoming Interfac:</b>	internal
<b>Source Address:</b>	all
<b>Outgoing Interface:</b>	external
<b>Destination Address:</b>	RP
<b>Schedule:</b>	always
<b>Service:</b>	ALL
<b>Action:</b>	ACCEPT

Select *OK*.

- 2nd policy

Select *Create New*

Use the following settings:

<b>Policy Type:</b>	Firewall
<b>Policy Subtype:</b>	Address
<b>Incoming Interfac:</b>	external
<b>Source Address:</b>	RP
<b>Outgoing Interface:</b>	internal
<b>Destination Address:</b>	all
<b>Schedule:</b>	always
<b>Service:</b>	ALL
<b>Action:</b>	ACCEPT

Select *OK*.

5. Add the multicast security policy.  
Go to Policy > Policy > Multicast Policy  
Select *Create New*  
Use the following settings:

<b>Incoming Interface:</b>	external
<b>Source Address:</b>	multicast_source_subnet
<b>Outgoing Interface:</b>	internal
<b>Destination Address:</b>	multicast_stream
<b>Protocol:</b>	Any
<b>Action:</b>	ACCEPT

Select *OK*.

6. Add an access list. (CLI only)

```
config router access-list
  edit Source-RP
    config rule
      edit 1
        set prefix 233.254.200.0 255.255.255.0
        set exact-match disable
      next
    end
```

7. Add some static routes.

Go to *Router > Static > Static Routes*.

- Route 1

Select *Create New*.

Use the following settings:

<b>Destination IP/Mask:</b>	0.0.0.0/0.0.0.0
<b>Device:</b>	internal
<b>Gateway:</b>	10.31.130.250

Select *OK*.

- Route 2

Select *Create New*.

Use the following settings:

<b>Destination IP/Mask:</b>	169.254.0.0/16
<b>Device:</b>	external
<b>Gateway:</b>	10.31.138.250

Select *OK*.

8. Configure multicast routing.

Go to *Router > Dynamic > Multicast*.

Add the following Static Rendezvous Point(s):

- 169.254.100.1
- Route 1  
Select *Create New*.

Use the following settings:

<b>Interface:</b>	internal
<b>PIM Mode:</b>	Sparse Mode
<b>DR Priority:</b>	<not needed in this scenario>
<b>RP Candidate:</b>	<not needed in this scenario>
<b>RP Candidate Priority:</b>	<not needed in this scenario>

Select *OK*.

- Route 2  
Select *Create New*.

Use the following settings:

<b>Interface:</b>	external
<b>PIM Mode:</b>	Sparse Mode
<b>DR Priority:</b>	
<b>RP Candidate:</b>	
<b>RP Candidate Priority:</b>	

Select *OK*.

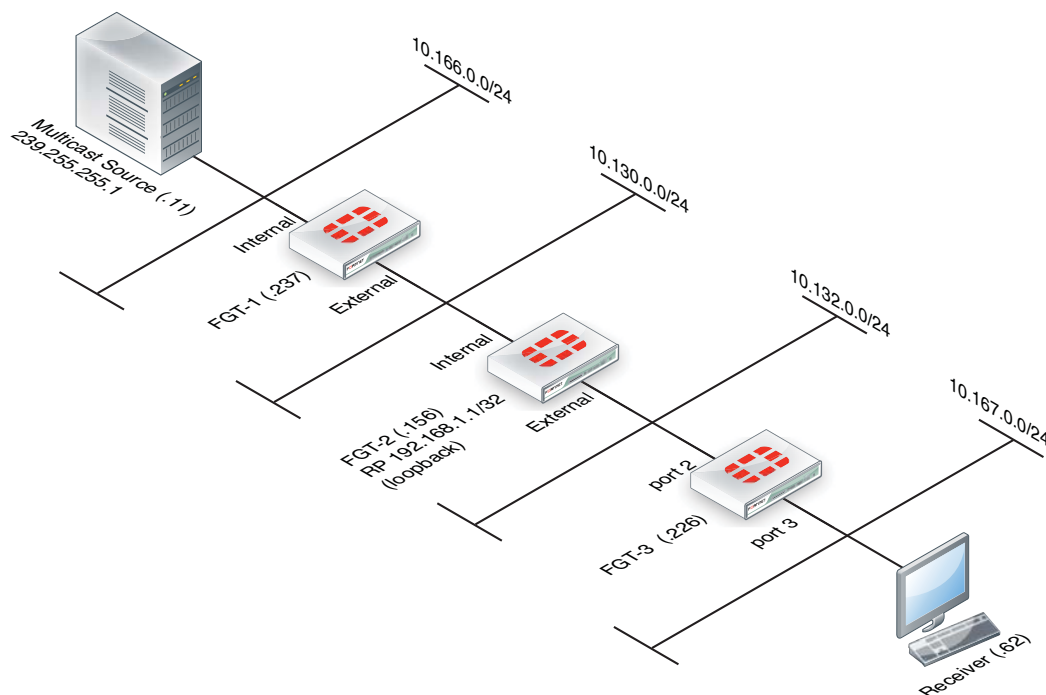

### Cisco\_3750\_3 router configuration

```
version 12.2
!
hostname Cisco-3750-3
!
switch 1 provision ws-c3750-24ts
ip subnet-zero
ip routing
!
ip multicast-routing distributed
!
spanning-tree mode pvst
no spanning-tree optimize bpdu transmission
spanning-tree extend system-id
!
interface FastEthernet1/0/23
    switchport access vlan 128
    switchport mode access
!
interface FastEthernet1/0/24
    switchport access vlan 130
    switchport mode access
!
interface Vlan128
    ip address 10.31.128.130 255.255.255.252
    ip pim sparse-mode
    ip mroute-cache distributed
!
interface Vlan130
    ip address 10.31.130.250 255.255.255.0
    ip pim sparse-mode
    ip mroute-cache distributed
!
ip classless
ip route 0.0.0.0 0.0.0.0 10.31.130.1
ip http server
ip pim rp-address 169.254.100.1 Source-RP
!
!
ip access-list standard Source-RP
permit 233.254.200.0 0.0.0.255
```

### FortiGate PIM-SM debugging examples

Using the example topology shown in [Figure 178](#) you can trace the multicast streams and states within the three FortiGate units (FGT-1, FGT-2, and FGT-3) using the debug commands described in this section. The command output in this section is taken from FortiGate unit when the multicast stream is flowing correctly from source to receiver.

**Figure 178:**PIM-SM debugging topology

### Checking that the receiver has joined the required group

From the last hop router, FGT-3, you can use the following command to check that the receiver has correctly joined the required group.

```
FGT-3 # get router info multicast igmp groups
```

```
IGMP Connected Group Membership
```

Group Address	Interface	Uptime	Expires	Last Reporter
239.255.255.1	port3	00:31:15	00:04:02	10.167.0.62

Only 1 receiver is displayed for a particular group, this is the device that responded to the IGMP query request from the FGT-3. If a receiver is active the expire time should drop to approximately 2 minutes before being refreshed.

### Checking the PIM-SM neighbors

Next the PIM-SM neighbors should be checked. A PIM router becomes a neighbor when the PIM router receives a PIM hello. Use the following command to display the PIM-SM neighbors of FGT-3.

```
FGT-3 # get router info multicast pim sparse-mode neighbour
```

Neighbor Address	Interface	Priority/Mode	Uptime/Expires	Ver	DR
10.132.0.156	port2		01:57:12/00:01:33	v2	1 /

## Checking that the PIM router can reach the RP

The rendezvous point (RP) must be reachable for the PIM router (FGT-3) to be able to send the \*,G join to request the stream. This can be checked for FGT-3 using the following command:

```
FGT-3 # get router info multicast pim sparse-mode rp-mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/4, Static
RP: 192.168.1.1
Uptime: 07:23:00
```

## Viewing the multicast routing table (FGT-3)

The FGT-3 unicast routing table can be used to determine the path taken to reach the RP at 192.168.1.1. You can then check the stream state entries using the following commands:

```
FGT-3 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

(*,*,RP) Entries	This state may be reached by general joins for all groups served by a specified RP.
(*,G) Entries	State that maintains the RP tree for a given group.
(S,G) Entries	State that maintains a source-specific tree for source s and group G.
(S,G,rpt) Entries	State that maintains source-specific information about source s on the RP tree for G. For example, if a source is being received on the source-specific tree, it will normally have been pruned off the RP tree.
FCR	The FCR state entries are for tracking the sources in the <*, G> when <S, G> is not available for any reason, the stream would typically be flowing when this state exists.

Breaking down each entry in detail:

```
(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: JOINED
Local:
    port3
Joined:
Asserted:
FCR:
```

The RP will always be listed in a \*,G entry, the RPF neighbor and interface index will also be shown. In this topology these are the same in all downstream PIM routers. The state is active so the upstream state is joined.

In this case FGT-3 is the last hop router so the IGMP join is received locally on port3. There is no PIM outgoing interface listed for this entry as it is used for the upstream PIM join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.132.0.156
RPF idx: port2
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
Asserted:
Outgoing:
    port3
```

This is the entry for the SPT, no RP IS listed. The S, G stream will be forwarded out of the stated outgoing interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: NOT PRUNED
Local:
Pruned:
Outgoing:
```

The above S, G, RPT state is created for all streams that have both a S, G and a \*, G entry on the router. This is not pruned in this case because of the topology, the RP and source are reachable over the same interface.

Although not seen in this scenario, assert states may be seen when multiple PIM routers exist on the same LAN which can lead to more than one upstream router having a valid forwarding state. Assert messages are used to elect a single forwarder from the upstream devices.

## Viewing the PIM next-hop table

The PIM next-hop table is also very useful for checking the various states, it can be used to quickly identify the states of multiple multicast streams

```
FGT-3 # get router info multicast pim sparse-mode next-hop
```

Flags: N = New, R = RP, S = Source, U = Unreachable

Destination	Type	Nexthop	Nexthop	Nexthop	Metric	Pref
Refcnt		Num	Addr	Ifindex		
10.166.0.11	..S.	1	10.132.0.156	9 21	110	3
192.168.1.1	.R..	1	10.132.0.156	9 111	110	2

## Viewing the PIM multicast forwarding table

Also you can check the multicast forwarding table showing the ingress and egress ports of the multicast stream.

```
FGT-3 # get router info multicast table

IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL threshold)

(10.166.0.11, 239.255.255.1), uptime 04:02:55, stat expires 00:02:25
Owner PIM-SM, Flags: TF
  Incoming interface: port2
  Outgoing interface list:
    port3 (TTL threshold 1)
```

## Viewing the kernel forwarding table

Also the kernel forwarding table can be verified, however this should give similar information to the above command:

```
FGT-3 # diag ip multicast mroute
grp=239.255.255.1 src=10.166.0.11 intf=9 flags=(0x10000000)[  ]
  status=resolved
    last_assert=2615136 bytes=1192116 pkt=14538 wrong_if=0 num_ifs=1
    index(ttl)=[6(1),]
```

## Viewing the multicast routing table (FGT-2)

If you check the output on FGT-2 there are some small differences:

```
FGT-2 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0

(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: JOINED
  Local:
  Joined:
    external
  Asserted:
FCR:
```

The \*,G entry now has a joined interface rather than local because it has received a PIM join from FGT-3 rather than a local IGMP join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.130.0.237
RPF idx: internal
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
    external
Asserted:
Outgoing:
    external
```

The S,G entry shows that we have received a join on the external interface and the stream is being forwarded out of this interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: PRUNED
Local:
Pruned:
Outgoing:
    External
```

The S,G,RPT is different from FGT-3 because FGT-2 is the RP, it has pruned back the SPT for the RP to the first hop router.

### Viewing the multicast routing table (FGT-1)

FGT-1 again has some differences with regard to the PIM-SM states, there is no \*,G entry because it is not in the path of a receiver and the RP.

```
FGT-1_master # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

Below the S,G is the SPT termination because this FortiGate unit is the first hop router, the RPF neighbor always shows as 0.0.0.0 because the source is local to this device. Both the joined and outgoing fields show as external because the PIM join and the stream is egressing on this interface.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 0.0.0.0
RPF idx: None
SPT bit: 1
Upstream State: JOINED
```

```
Local:
Joined:
    external
Asserted:
Outgoing:
    external
```

The stream has been pruned back from the RP because the end-to-end SPT is flowing, there is no requirement for the stream to be sent to the RP in this case.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 0.0.0.0
RPF nbr: 10.130.0.156
RPF idx: external
Upstream State: RPT NOT JOINED
Local:
Pruned:
Outgoing:
```

## Example multicast destination NAT (DNAT) configuration

The example topology shown in [Figure 179](#) and described below shows how to configure destination NAT (DNAT) for two multicast streams. Both of these streams originate from the same source IP address, which is 10.166.0.11. The example configuration keeps the streams separate by creating 2 multicast NAT policies.

In this example the FortiGate units in [Figure 179](#) have the following roles:

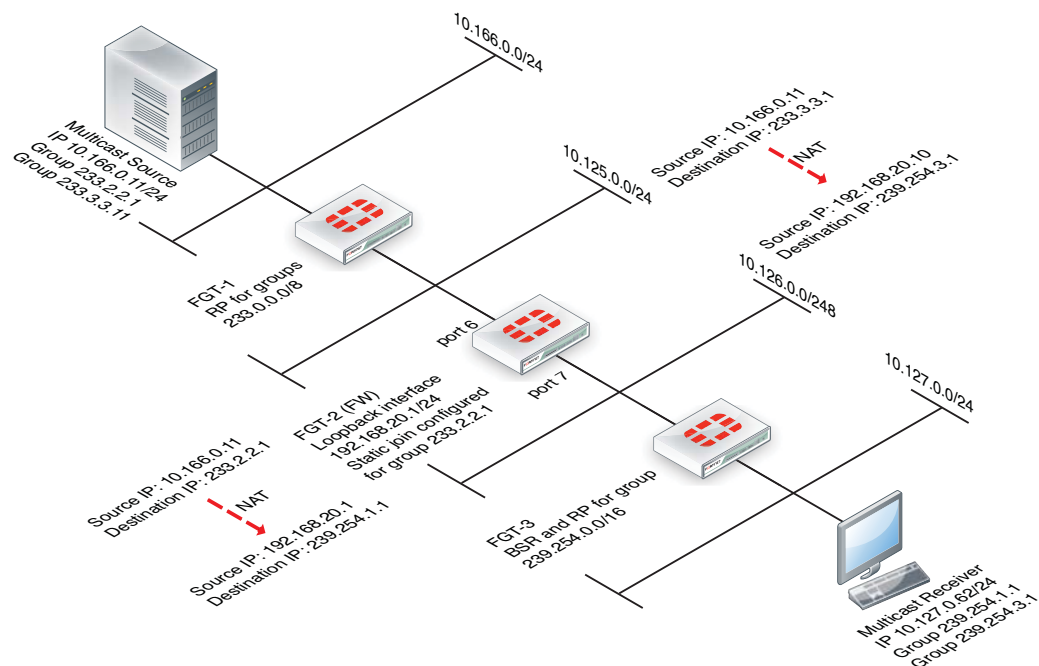

- FGT-1 is the RP for dirty networks, 233.0.0.0/8.
- FGT-2 performs all firewall and DNAT translations.
- FGT-3 is the RP for the clean networks, 239.254.0.0/16.
- FGT-1 and FGT-3 are functioning as PM enabled routers and could be replaced can be any PIM enabled router.

This example only describes the configuration of FGT-2.

FGT-2 performs NAT so that the receivers connected to FGT-3 receive the following translated multicast streams.

- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.2.2.1; FGT-3 translates the source and destination IPs to 192.168.20.1 and 239.254.1.1
- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.3.3.1; FGT-3 translates the source and destination IPs to 192.168.20.10 and 239.254.3.1

**Figure 179:**Example multicast DNAT topology

### To configure FGT-2 for DNAT multicast

1. Add a loopback interface. In the example, the loopback interface is named loopback.

```
config system interface
    edit loopback
        set vdom root
        set ip 192.168.20.1 255.255.255.0
        set type loopback
    next
end
```

2. Add PIM and add a unicast routing protocol to the loopback interface as if it was a normal routed interface. Also add static joins to the loopback interface for any groups to be translated.

```
config router multicast
    config interface
        edit loopback
            set pim-mode sparse-mode
            config join-group
                edit 233.2.2.1
                next
                edit 233.3.3.1
                next
            end
        next
    end
```

3. In this example, to add firewall multicast policies, different source IP addresses are required so you must first add an IP pool:

```
config firewall ippool
    edit Multicast_source
        set endip 192.168.20.20
        set interface port6
        set startip 192.168.20.10
    next
end
```

4. Add the translation security policies.

Policy 2, which is the source NAT policy, uses the actual IP address of port6. Policy 1, the DNAT policy, uses an address from the IP pool.

```
config firewall multicast-policy
    edit 1
        set dnat 239.254.3.1
        set dstaddr example-addr_P
        set dstintf loopback
        set nat 192.168.20.10
        set srcaddr example-addr_Q
        set srcintf port6
    next
    edit 2
        set dnat 239.254.1.1
        set dstaddr example-addr_R
        set dstintf loopback
        set nat 192.168.20.1
        set srcaddr example-addr_Q
        set srcintf port6
    next
end
```

5. Add a firewall multicast policy to forward the stream from the loopback interface to the physical outbound interface.

This example is an any/any policy that makes sure traffic accepted by the other multicast policies can exit the FortiGate unit.

```
config firewall multicast-policy
    edit 3
        set dstintf port7
        set srcintf loopback
    next
end
```

## Example PIM configuration that uses BSR to find the RP

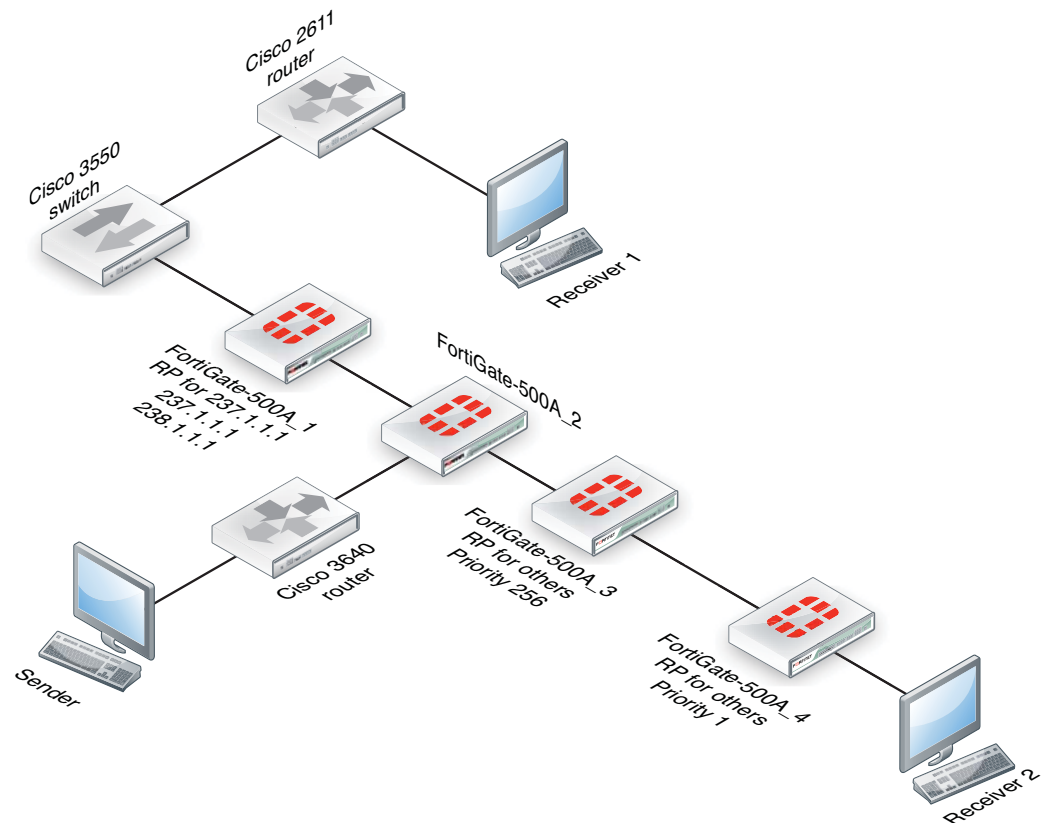

This example shows how to configure a multicast routing network for a network consisting of four FortiGate-500A units (FortiGate-500A\_1 to FortiGate-500A\_4, see [Figure 180](#)). A multicast sender is connected to FortiGate-500A\_2. FortiGate-500A\_2 forwards multicast packets in two directions to reach Receiver 1 and Receiver 2.

The configuration uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the `236.1.1.1` group (source).

This example describes:

- [Commands used in this example](#)
- [Configuration steps](#)
- [Example debug commands](#)

**Figure 180:** PIM network topology using BSR to find the RP

### Commands used in this example

This example uses CLI commands for the following configuration settings:

- [Adding a loopback interface \(lo0\)](#)
- [Defining the multicast routing](#)
- [Adding the NAT multicast policy](#)

## Adding a loopback interface (lo0)

Where required, the following command is used to define a loopback interface named lo0.

```
config system interface
  edit lo0
    set vdom root
    set ip 1.4.50.4 255.255.255.255
    set allowaccess ping https ssh snmp http telnet
    set type loopback
  next
end
```

## Defining the multicast routing

In this example, the following command syntax is used to define multicast routing. The example uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface lo0 must join the 236.1.1.1 group (source).

```
config router multicast
  config interface
    edit port6
      set pim-mode sparse-mode
    next
    edit port1
      set pim-mode sparse-mode
    next
    edit lo0
      set pim-mode sparse-mode
      set rp-candidate enable
      config join-group
        edit 236.1.1.1
        next
      end
      set rp-candidate-priority 1
    next
  end
set multicast-routing enable
config pim-sm-global
  set bsr-allow-quick-refresh enable
  set bsr-candidate enable
  set bsr-interface lo0
  set bsr-priority 200
end
end
```

## Adding the NAT multicast policy

In this example, the incoming multicast policy does the address translation. The NAT address should be the same as the IP address of the of loopback interface. The DNAT address is the translated address, which should be a new group.

```
config firewall multicast-policy
  edit 1
    set dstintf port6
    set srcintf lo0
  next
  edit 2
    set dnat 238.1.1.1
    set dstintf lo0
    set nat 1.4.50.4
    set srcintf port1
  next
```

## Configuration steps

In this sample, FortiGate-500A\_1 is the RP for the group 228.1.1.1, 237.1.1.1, 238.1.1.1, and FortiGate-500A\_4 is the RP for the other group which has a priority of 1. OSPF is used in this example to distribute routes including the loopback interface. All firewalls have full mesh security policies to allow any to any.

- In the FortiGate-500A\_1 configuration, the NAT policy translates source address 236.1.1.1 to 237.1.1.1
- In the FortiGate-500A\_4, configuration, the NAT policy translates source 236.1.1.1 to 238.1.1.1
- Source 236.1.1.1 is injected into network as well.

The following procedures include the CLI commands for configuring each of the FortiGate units in the example configuration.

### To configure FortiGate-500A\_1

#### 1. Configure multicast routing.

```
config router multicast
  config interface
    edit port5
      set pim-mode sparse-mode
    next
    edit port4
      set pim-mode sparse-mode
    next
    edit lan
      set pim-mode sparse-mode
    next
    edit port1
      set pim-mode sparse-mode
    next
    edit lo999
      set pim-mode sparse-mode
    next
```

```

        edit lo0
            set pim-mode sparse-mode
            set rp-candidate enable
            set rp-candidate-group 1
        next
    end
    set multicast-routing enable
    config pim-sm-global
        set bsr-candidate enable
        set bsr-interface lo0
    end
end

```

## 2. Add multicast security policies.

```

config firewall multicast-policy
    edit 1
        set dstintf port5
        set srcintf port4
    next
    edit 2
        set dstintf port4
        set srcintf port5
    next
    edit 3
    next
end

```

## 3. Add router access lists.

```

config router access-list
    edit 1
        config rule
            edit 1
                set prefix 228.1.1.1 255.255.255.255
                set exact-match enable
            next
            edit 2
                set prefix 237.1.1.1 255.255.255.255
                set exact-match enable
            next
            edit 3
                set prefix 238.1.1.1 255.255.255.255
                set exact-match enable
            next
        end
    next
end

```

## To configure FortiGate-500A\_2

### 1. Configure multicast routing.

```
config router multicast
  config interface
    edit "lan"
      set pim-mode sparse-mode
    next
    edit "port5"
      set pim-mode sparse-mode
    next
    edit "port2"
      set pim-mode sparse-mode
    next
    edit "port4"
      set pim-mode sparse-mode
    next
    edit "lo_5"
      set pim-mode sparse-mode
      config join-group
        edit 236.1.1.1
        next
      end
    next
  end
  set multicast-routing enable
end
```

### 2. Add multicast security policies.

```
config firewall multicast-policy
  edit 1
    set dstintf lan
    set srcintf port5
  next
  edit 2
    set dstintf port5
    set srcintf lan
  next
  edit 4
    set dstintf lan
    set srcintf port2
  next
  edit 5
    set dstintf port2
    set srcintf lan
  next
  edit 7
    set dstintf port1
    set srcintf port2
  next
  edit 8
```

```

        set dstintf port2
        set srcintf port1
    next
    edit 9
        set dstintf port5
        set srcintf port2
    next
    edit 10
        set dstintf port2
        set srcintf port5
    next
    edit 11
        set dnat 237.1.1.1
        set dstintf lo_5
        set nat 5.5.5.5
        set srcintf port2
    next
    edit 12
        set dstintf lan
        set srcintf lo_5
    next
    edit 13
        set dstintf port1
        set srcintf lo_5
    next
    edit 14
        set dstintf port5
        set srcintf lo_5
    next
    edit 15
        set dstintf port2
        set srcintf lo_5
    next
    edit 16
    next
end

```

### **To configure FortiGate-500A\_3**

#### **1. Configure multicast routing.**

```

config router multicast
    config interface
        edit port5
            set pim-mode sparse-mode
        next
        edit port6
            set pim-mode sparse-mode
        next
        edit lo0
            set pim-mode sparse-mode
    next
end

```

```

        set rp-candidate enable
        set rp-candidate-priority 255
    next
    edit lan
        set pim-mode sparse-mode
    next
end
set multicast-routing enable
config pim-sm-global
    set bsr-candidate enable
    set bsr-interface lo0
end
end

```

## 2. Add multicast security policies.

```

config firewall multicast-policy
    edit 1
        set dstintf port5
        set srcintf port6
    next
    edit 2
        set dstintf port6
        set srcintf port5
    next
    edit 3
        set dstintf port6
        set srcintf lan
    next
    edit 4
        set dstintf lan
        set srcintf port6
    next
    edit 5
        set dstintf port5
        set srcintf lan
    next
    edit 6
        set dstintf lan
        set srcintf port5
    next
end

```

## To configure FortiGate-500A\_4

### 1. Configure multicast routing.

```
config router multicast
  config interface
    edit port6
      set pim-mode sparse-mode
    next
    edit lan
      set pim-mode sparse-mode
    next
    edit port1
      set pim-mode sparse-mode
    next
    edit lo0
      set pim-mode sparse-mode
      set rp-candidate enable
      config join-group
        edit 236.1.1.1
      next
      end
      set rp-candidate-priority 1
    next
  end
set multicast-routing enable
config pim-sm-global
  set bsr-allow-quick-refresh enable
  set bsr-candidate enable
  set bsr-interface lo0
  set bsr-priority 1
end
end
```

### 2. Add multicast security policies.

```
config firewall policy
  edit 1
    set srcintf lan
    set dstintf port6
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 2
    set srcintf port6
    set dstintf lan
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
```

```

        set service ANY
    next
edit 3
    set srcintf port1
    set dstintf port6
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
next
edit 4
    set srcintf port6
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
next
edit 5
    set srcintf port1
    set dstintf lan
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
next
edit 6
    set srcintf lan
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
next
edit 7
    set srcintf port1
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
next
edit 8
    set srcintf port6

```

```

        set dstintf lo0
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
edit 9
    set srcintf port1
    set dstintf lo0
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
next
edit 10
    set srcintf lan
    set dstintf lo0
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
next
end

```

## Example debug commands

You can use the following CLI commands to view information about and status of the multicast configuration. This section includes `get` and `diagnose` commands and some sample output.

```
get router info multicast pim sparse-mode table 236.1.1.1
```

```
get router info multicast pim sparse-mode neighbor
```

Neighbor Address Mode	Interface	Uptime/Expires	Ver	DR	Priority/ Priority/
83.97.1.2	port6	02:22:01/00:01:44	v2	1 / DR	

```
diagnose ip multicast mroute
```

```
grp=236.1.1.1 src=19.2.1.1 intf=7 flags=(0x10000000) [  ]
```

```
status=resolved
```

```

# Chapter 8 Hardware Acceleration

This FortiOS Handbook chapter contains the following sections:

[Hardware acceleration overview](#) describes the capabilities of FortiGate content processors (CPs), security processors (SPs) and network processors (NPs). This chapter also describes how to determine the hardware acceleration components installed in your FortiGate unit and contains some configuration details and examples.

[NP6 Acceleration](#) describes the FortiGate NP6 network processor.

[FortiGate NP6 architectures](#) contains details about the network processing architectures of FortiGate units that contain NP6 processors.

[NP4 Acceleration](#) describes the FortiGate NP4 network processor.

[FortiGate NP4 architectures](#) contains details about the network processing architectures of FortiGate units that contain NP4 processors.

# Hardware acceleration overview

All FortiGate models have specialized acceleration hardware that can offload resource intensive processing from main processing (CPU) resources. All FortiGate units include specialized content processors (CPs) that accelerate a wide range of important security processes such as virus scanning, attack detection, encryption and decryption. Many FortiGate models also contain security processors (SPs) that accelerate processing for specific security features such as IPS and network processors (NPs) that offload processing of high volume network traffic.

This chapter contains the following topics:

- [Content processors \(CP4, CP5, CP6 and CP8\)](#)
- [Security processors \(SPs\)](#)
- [Network processors \(NP1, NP2, NP3, NP4 and NP6\)](#)
- [Checking that traffic is offloaded by NP processors](#)
- [Controlling IPS NPx and CPx acceleration](#)

## Content processors (CP4, CP5, CP6 and CP8)

All FortiGate units contain FortiASIC Content Processors (CPs) that accelerate many common resource intensive security related processes. CPs work at the system level with tasks being offloaded to them as determined by the main CPU. Capabilities of the CPs vary by model. Newer FortiGate units include CP8 processors. Older CP versions still in use in currently operating FortiGate models include the CP4, CP5, and CP6.

### CP8 capabilities

The CP8 content processor provides the following services:

- IPS signature matching acceleration
- High performance VPN bulk data engine
  - IPSEC and SSL/TLS protocol processor
  - DES/3DES/AES in accordance with FIPS46-3/FIPS81/FIPS197
  - ARC4 in compliance with RC4
  - MD5/SHA-1/SHA256 with RFC1321 and FIPS180
  - HMAC in accordance with RFC2104/2403/2404 and FIPS198
- Key Exchange Processor support high performance IKE and RSA computation
  - Public key exponentiation engine with hardware CRT support
  - Primarily checking for RSA key generation
  - Handshake accelerator with automatic key material generation
  - Random Number generator compliance with ANSI X9.31
  - Sub public key engine (PKCE) to support up to 4094 bit operation directly
- Message authentication module offers high performance cryptographic engine for calculating SHA256/SHA1/MD5 of data up to 4G bytes (used by many applications)
- PCI express Gen 2 four lanes interface
- Cascade Interface for chip expansion

### CP6 capabilities

- Dual content processors
- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321 and FIPS180
- HMAC in accordance with RFC2104/2403/2404 and FIPS198
- IPsec protocol processor
- High performance IPsec engine
- Random Number generator compliance with ANSI X9.31
- Key exchange processor for high performance IKE and RSA computation
- Script Processor
- SSL/TLS protocol processor for SSL content scanning and SSL acceleration

### CP5 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321/2104/2403/2404 and FIPS180/FIPS198
- IPsec protocol processor
- High performance IPSEC Engine
- Random Number generator compliant with ANSI X9.31
- Public Key Crypto Engine supports high performance IKE and RSA computation
- Script Processor

### CP4 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC
- IPSEC protocol processor
- Random Number generator
- Public Key Crypto Engine
- Content processing engine
- ANSI X9.31 and PKCS#1 certificate support

## Determining the content processor in your FortiGate unit

Use the `get hardware status` CLI command to determine which content processor your FortiGate unit contains. The output looks like this:

```
get hardware status
Model name: FortiGate-100D
ASIC version: CP8
ASIC SRAM: 64M
CPU: Intel(R) Atom(TM) CPU D525 @ 1.80GHz
Number of CPUs: 4
RAM: 1977 MB
Compact Flash: 15331 MB /dev/sda
Hard disk: 15272 MB /dev/sda
USB Flash: not available
Network Card chipset: Intel(R) PRO/1000 Network Connection (rev.0000)
Network Card chipset: bcm-sw Ethernet driver 1.0 (rev.)
```

The ASIC version line lists the content processor model number.

## Viewing SSL acceleration status

You can view the status of SSL acceleration using the following command:

```
get vpn status ssl hw-acceleration-status
Acceleration hardware detected: kxp=on cipher=on
```

## Disabling CP offloading

If you want to completely disable offloading to CP processors for test purposes or other reasons, you can do so in security policies. Here are some examples:

For IPv4 security policies.

```
config firewall policy
  edit 1
    set auto-asic-offload disable
  end
```

For IPv6 security policies.

```
config firewall policy6
  edit 1
    set auto-asic-offload disable
  end
```

For multicast security policies.

```
config firewall multicast-policy
  edit 1
    set auto-asic-offload disable
  end
```

## Security processors (SPs)

FortiGate Security Processing (SP) modules, such as the SP3 but also including the XG2, XE2, FE8, and CE4, work at both the interface and system level to increase overall system performance by accelerating specialized security processing. You can configure the SP to favor IPS over firewall processing in hostile high-traffic environments. The following security processors are available:

- The SP3 is built into the FortiGate-5101B and provides IPS acceleration. No special configuration is required. All IPS traffic is accelerated by the built-in SP3 processors.
- The FMC-XG2 is an FMC module with two 10Gb/s SPF+ interfaces that can be used on FortiGate-3950B and FortiGate-3951B units.
- The FortiGate-3140B also contains a built-in XG2 using ports 19 and 20.
- The ADM-XE2 is a dual-width AMC module with two 10Gb/s interfaces that can be used on FortiGate-3810A and FortiGate-5001A-DW systems.
- The ADM-FE8 is a dual-width AMC module with eight 1Gb/s interfaces that can be used with the FortiGate-3810A.
- The ASM-CE4 is a single-width AMC module with four 10/100/1000 Mb/s interfaces that can be used on FortiGate-3016B and FortiGate-3810A units.

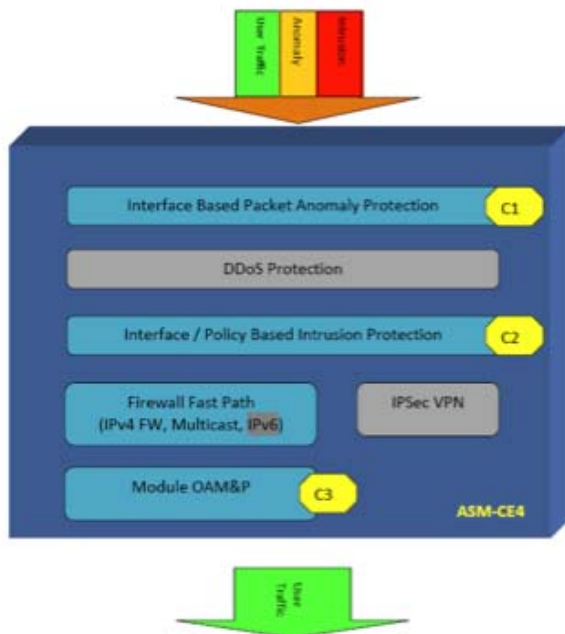

### SP Processing Flow

SP processors provide an integrated high performance fast path multilayer solution for both intrusion protection and firewall functions. The multilayered protection starts from anomaly checking at packet level to ensure each packet is sound and reasonable. Immediately after that, a sophisticated set of interface based packet anomaly protection, DDoS protection, policy based intrusion protection, firewall fast path, and behavior based methods are employed to prevent DDoS attacks from the rest of system.

Then the packets enter an interface/policy based intrusion protection system,

where each packet is evaluated against a set of signatures. The end result is streams of user packets that are free of anomaly and attacks, entering the fast path system for unicast or multicast fast path forwarding.

**Figure 181:**SP processing flow

## Displaying information about security processing modules

You can display information about installed SP modules using the CLI command

```
diagnose npu spm
```

For example, for the FortiGate-5101C:

```
FG-5101C # diagnose npu spm list
Available SP Modules:
```

ID	Model	Slot	Interface
0	xh0	built-in	port1, port2, port3, port4 base1, base2, fabric1, fabric2 eth10, eth11, eth12, eth13 eth14, eth15, eth16, eth17 eth18, eth19

You can also use this command to get more info about SP processing. This example shows how to display details about how the module is processing sessions using the syn proxy.

```
diagnose npu spm dos synproxy <sp_id>
```

This is a partial output of the command:

```
Number of proxied TCP connections : 0
Number of working proxied TCP connections : 0
Number of retired TCP connections : 0
Number of valid TCP connections : 0
Number of attacks, no ACK from client : 0
Number of no SYN-ACK from server : 0
Number of reset by server (service not supported): 0
Number of established session timeout : 0
Client timeout setting : 3 Seconds
Server timeout setting : 3 Seconds
```

## Network processors (NP1, NP2, NP3, NP4 and NP6)

FortiASIC network processors work at the interface level to accelerate traffic by offloading traffic from the main CPU. Current models contain NP4 and NP6 network processors. Older FortiGate models include NP1 network processors (also known as FortiAccel, or FA2) and NP2 network processors.

The traffic that can be offloaded, maximum throughput, and number of network interfaces supported by each varies by processor model:

- NP6 supports offloading of most IPv4 and IPv6 traffic, IPsec VPN encryption, CAPWAP traffic, and multicast traffic. The NP6 has a capacity of 40 Gbps through 4 x 10 Gbps interfaces or 3 x 10 Gbps and 16 x 1 Gbps interfaces. For details about the NP6 processor, see [“NP6 Acceleration” on page 1082](#) and for information about FortiGate models with NP6 processors, see [“FortiGate NP6 architectures” on page 1089](#).
- NP4 supports offloading of most IPv4 firewall traffic and IPsec VPN encryption. The NP4 has a capacity of 20 Gbps through 2 x 10 Gbps interfaces. For details about NP4 processors, see [“NP4 Acceleration” on page 1093](#) and for information about FortiGate models with NP4 processors, see [“FortiGate NP4 architectures” on page 1105](#).
- NP2 supports IPv4 firewall and IPsec VPN acceleration. The NP2 has a capacity of 2 Gbps through 2 x 10 Gbps interfaces or 4 x 1 Gbps interfaces.
- NP1 supports IPv4 firewall and IPsec VPN acceleration with 2 Gbps capacity. The NP1 has a capacity of 2 Gbps through 2 x 1 Gbps interfaces.
  - The NP1 does not support frames greater than 1500 bytes. If your network uses jumbo frames, you may need to adjust the MTU (Maximum Transmission Unit) of devices connected to NP1 ports. Maximum frame size for NP2, NP4, and NP6 processors is 9000 bytes.
  - For both NP1 and NP2 network processors, ports attached to a network processor cannot be used for firmware installation by TFTP.

Session that require proxy-based and flow based security features (for example, virus scanning, IPS, application control and so on) are not fast pathed and must be processed by the CPU.

---

## Determining the network processors installed on your FortiGate unit

Use the following command to list the NP6 processors in your FortiGate unit:

```
diagnose npu np6 port-list
```

To list other network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu <model> list
```

<model> can be legacy, np1, np2 or np4.

The output lists the interfaces that have the specified processor. For example, for a FortiGate-5001B:

```
get hardware npu np4 list
```

ID	Model	Slot	Interface
0	On-board		port1 port2 port3 port4 fabric1 base1 npu0-vlink0 npu0-vlink1
1	On-board		port5 port6 port7 port8 fabric2 base2 npu1-vlink0 npu1-vlink1

The npu0-vlink0, npu1-vlink1 etc interfaces are used for accelerating inter-VDOM links.

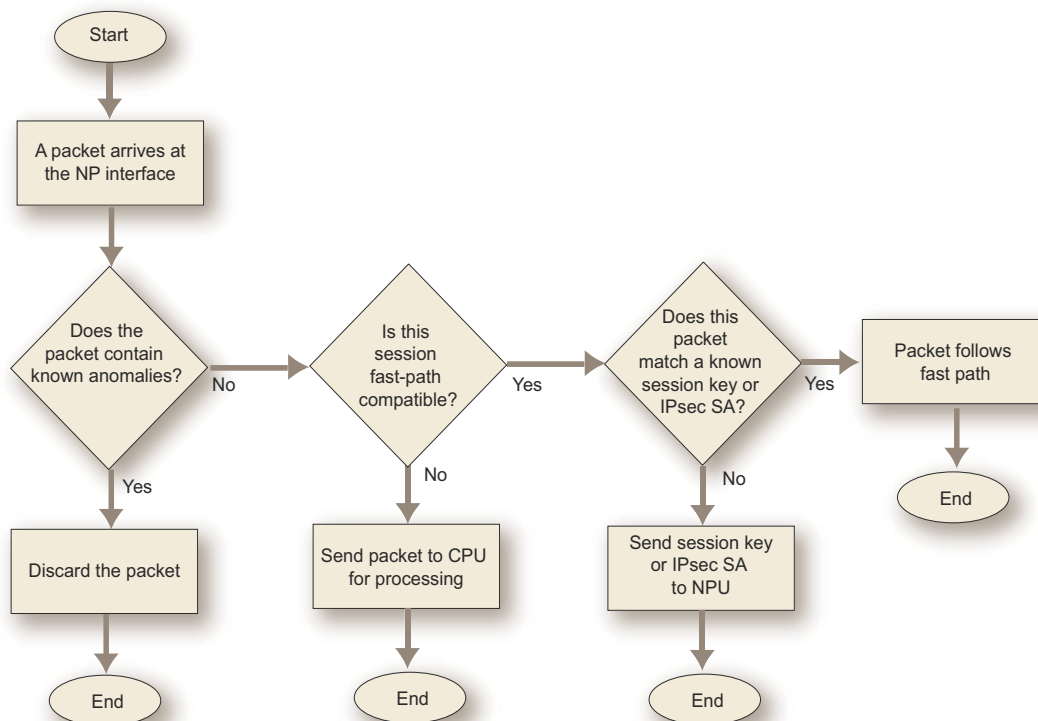

## How NP hardware acceleration alters packet flow

NP hardware acceleration generally alters packet flow as follows:

1. Packets initiating a session pass to the FortiGate unit's main processing resources (CPU).
2. The FortiGate unit assesses whether the session matches fast path (offload) requirements.  
To be suitable for offloading, traffic must possess only characteristics that can be processed by the fast path. The list of requirements depends on the processor, see [“NP6 session fast path requirements” on page 1083](#) or [“NP4 session fast path requirements” on page 1094](#).  
If the session can be fast pathed, the FortiGate unit sends the session key or IPsec security association (SA) and configured firewall processing action to the appropriate network processor.
3. Network processors continuously match packets arriving on their attached ports against the session keys and SAs they have received.
  - If a network processor's network interface is configured to perform hardware accelerated anomaly checks, the network processor drops or accepts packets which match the configured anomaly patterns. These checks are separate from and in advance of anomaly checks performed by IPS, which is not compatible with network processor offloading. See [“Offloading NP pre-IPS anomaly detection” on page 1076](#).
  - The network processor next checks for a matching session key or SA. If a matching session key or SA is found, and if the packet meets packet requirements, the network processor processes the packet according to the configured action and then sends the resulting packet. This is the actual offloading step. Performing this processing on the NP processor improves overall performance because the NP processor is optimized for this task. As well, overall FortiGate performance is improved because the CPU has fewer sessions to process.

**Figure 182:**NP network processor packet flow

- If a matching session key or SA is not found, or if the packet does not meet packet requirements, the packet cannot be offloaded. The network processor sends the data to the FortiGate unit's CPU, which processes the packet.

Encryption and decryption IPsec traffic originating from the FortiGate can utilize network processor encryption capabilities. See [“Configuring NP accelerated VPN encryption/decryption offloading” on page 1078](#).

Packet forwarding rates vary by the percentage of offloadable processing and the type of network processing required by your configuration, but are independent of frame size. For optimal traffic types, network throughput can equal wire speed.

## NP processors and traffic logging and monitoring

Except for the NP6, network processors do not count offloaded packets, and offloaded packets are not logged by traffic logging and are not included in traffic statistics and traffic log reports.

NP6 processors support per-session traffic and byte counters, Ethernet MIB matching, and reporting through messages resulting in traffic statistics and traffic log reporting.

## NP session offloading in HA active-active configuration

Network processors can improve network performance in active-active (load balancing) high availability (HA) configurations, even though traffic deviates from general offloading patterns, involving more than one network processor, each in a separate FortiGate unit. No additional offloading requirements apply.

Once the primary FortiGate unit's main processing resources send a session key to its network processor(s), network processor(s) on the primary unit can redirect any subsequent session

traffic to other cluster members, reducing traffic redirection load on the primary unit's main processing resources.

As subordinate units receive redirected traffic, each network processor in the cluster assesses and processes session offloading independently from the primary unit. Session key states of each network processor are not part of synchronization traffic between HA members.

## Configuring NP HMAC check offloading

Hash-based Message Authentication Code (HMAC) checks offloaded to network processors by default. You can enter the following command to disable this feature:

```
configure system global
    set ipsec-hmac-offload disable
end
```

## Offloading NP pre-IPS anomaly detection

Network interfaces associated with a port attached to a network processor can be configured to offload anomaly checking. This anomaly checking happens before other offloading and separately from and in advance of DoS policy anomaly checking. Using the following command, each FortiGate interface can have a different anomaly checking configuration.

```
config system interface
    edit <port-name>
        set fp-anomaly <anomalies>
    end
```

where <anomalies> can be one, more than one or all of the following:

Anomaly	Description
drop_icmp_frag	Drop ICMP fragments to pass.
drop_icmpland	Drop ICMP Land.
drop_ipland	Drop IP Land.
drop_iplsrr	Drop IP with Loose Source Record Route option.
drop_iprr	Drop IP with Record Route option.
drop_ipsecurity	Drop IP with Security option.
drop_ipssrr	Drop IP with Strict Source Record Route option.
drop_ipstream	Drop IP with Stream option.
drop_iptimestamp	Drop IP with Timestamp option.
drop_ipunknown_option	Drop IP with malformed option.
drop_ipunknown_prot	Drop IP with Unknown protocol.
drop_tcp_fin_noack	Drop TCP FIN with no ACT flag set to pass.
drop_tcp_no_flag	Drop TCP with no flag set to pass.
drop_tcpland	Drop TCP Land.

Anomaly	Description
drop_udpland	Drop UDP Land.
drop_winnuke	Drop TCP WinNuke.
pass_icmp_frag	Allow ICMP fragments to pass.
pass_icmpland	Allow ICMP Land to pass.
pass_ipland	Allow IP land to pass.
pass_iplsrr	Allow IP with Loose Source Record Route option to pass.
pass_iprr	Allow IP with Record Route option to pass.
pass_ipsecurity	Allow IP with Security option to pass.
pass_ipssrr	Allow IP with Strict Source Record Route option to pass.
pass_ipstream	Allow IP with Stream option to pass.
pass_iptimestamp	Allow IP with Timestamp option to pass.
pass_ipunknown_option	Allow IP with malformed option to pass.
pass_ipunknown_prot	Allow IP with Unknown protocol to pass.
pass_tcp_fin_noack	Allow TCP FIN with no ACK flag set to pass.
pass_tcp_no_flag	Allow TCP with no flag set to pass.
pass_tcpland	Allow TCP Land to pass.
pass_udpland	Allow UDP Land to pass.
pass_winnuke	Allow TCP WinNuke to pass.

### Example

You might configure an NP4 to drop packets with TCP WinNuke or unknown IP protocol anomalies, but to pass packets with an IP time stamp, using hardware acceleration provided by the network processor.

```
config system interface
    edit port1
        set fp-anomaly drop_winnuke drop_ipunknown_prot pass_iptimestamp
    end
```

## Software switch interfaces and NP processors

FortiOS supports creating a software switch by grouping two or more FortiGate physical interfaces into a single virtual or software switch interface. All of the interfaces in this virtual switch act like interfaces in a hardware switch in that they all have the same IP address and can be connected to the same network. You create a software switch interface from the CLI using the command `config system switch-interface`.

The software switch is a bridge group of several interfaces, and the FortiGate CPU maintains the mac-port table for this bridge. As a result of this CPU involvement, traffic processed by a software switch interface is not offloaded to network processors.

## Configuring NP accelerated VPN encryption/decryption offloading

Network processing unit (npu) settings configure offloading behavior for IPsec VPN. Configured behavior applies to all network processors contained by the FortiGate unit itself or any installed AMC modules.

```
config system npu
    set enc-offload-antireplay {enable | disable}
    set dec-offload-antireplay {enable | disable}
    set offload-ipsec-host {enable | disable}
end
```

Variables	Description	Default
enc-offload-antireplay {enable   disable}	Enable or disable offloading of IPsec encryption.  This option is used only when replay detection is enabled in Phase 2 configuration. If replay detection is disabled, encryption is always offloaded.	disable
dec-offload-antireplay {enable   disable}	Enable or disable offloading of IPsec decryption.  This option is used only when replay detection is enabled in Phase 2 configuration. If replay detection is disabled, decryption is always offloaded.	enable
offload-ipsec-host {enable   disable}	Enable or disable offloading of IPsec encryption of traffic from local host (FortiGate unit).  <b>Note:</b> For this option to take effect, the FortiGate unit must have previously sent the security association (SA) to the network processor.	disable

### Example

You could configure the offloading of encryption and decryption for an IPsec SA that was sent to the network processor.

```
config system npu
    set enc-offload-antireplay enable
    set dec-offload-antireplay enable
    set offload-ipsec-host enable
end
```

## Checking that traffic is offloaded by NP processors

A number of diagnose commands can be used to verify that traffic is being offloaded.

## Using the packet sniffer

Use the packet sniffer to verify that traffic is offloaded. Offloaded traffic is not picked up by the packet sniffer so if you are sending traffic through the FortiGate unit and it is not showing up on the packet sniffer you can conclude that it is offloaded.

```
diag sniffer packet port1 <option>
```

## Checking the firewall session offload tag

Use the `diagnose sys session list` command to display sessions. If the output for a session includes the `npu info` field you should see information about session being offloaded. If the output doesn't contain an `npu info` field then the session has not been offloaded.

```
diagnose sys session list
session info: proto=6 proto_state=01 duration=34 expire=3565
              timeout=3600 flags=00000000 sockflag=00000000 sockport=0
              av_idx=0 use=3
origin-shaper=

```

## Verifying IPsec VPN traffic offloading

The following commands can be used to verify IPsec VPN traffic offloading to NP processors.

```
diagnose vpn ipsec status
```

```
NP1/NP2/NP4_0/sp_0_0:
```

```
    null:    0        0
    des:     0        0
    3des:   4075    4074
    aes:     0        0
    aria:    0        0
    seed:    0        0
    null:    0        0
    md5:    4075    4074

## Controlling IPS NPx and CPx acceleration

You can use the following commands to enable or disable acceleration of IPS processing by NPx and CPx processors:

```

config ips global
    set np-accel-mode {none | basic}
    set cp-accel-mode {none | basic | advanced}
end

```

The network processor (NP) acceleration modes are:

none: Network Processor acceleration disabled  
basic: Basic Network Processor acceleration enabled

The content processor (CP) acceleration modes are:

none: Content Processor acceleration disabled  
basic: Basic Content Processor acceleration enabled  
advanced: Advanced Content Processor acceleration enabled

# NP6 Acceleration

NP6 network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP6 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP6 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP6 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP6 processor plus the network processing load is removed from the CPU. In addition the NP6 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

Session keys (and IPsec SA keys) are stored in the memory of the NP6 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP6. There is no dependence on getting the right pair of interfaces since the offloading is done by the receiving NP6. The key to making this possible is the Integrated Switch Fabric (ISF) that connects the NP6s and the FortiGate unit interfaces together. The ISF allows any port connectivity. All ports and NP6s can communicate with each other over the ISF.

There are no special ingress and egress fast path requirements as long as traffic enters and exits on interfaces connected to the same ISF and the NP6 processors. All FortiGate models with NP6 processors connect all interfaces and NP6 processors to the same ISF (except management interfaces) so this should not ever be a problem.

There are at least two limitations to keep in mind:

- The capacity of each NP6 processor. An individual NP6 processor can support between 10 and 16 million sessions. This number is limited by the amount of memory the processor has. Once an NP6 processor hits its session limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP6 processors. To be able to do this you need to be aware of which interfaces connect to which NP6 processors and distribute incoming traffic accordingly.
- Some FortiGate units may use some NP6 processors for special functions. For example, ports 25 to 32 of the FortiGate-3700D can be used for low latency offloading. See [“FortiGate-3700D fast path architecture” on page 1091](#) for more information.

This chapter contains the following topics:

- [NP6 session fast path requirements](#)
- [Viewing your FortiGate NP6 processor configuration](#)
- [Increasing NP6 offloading capacity using link aggregation groups \(LAGs\)](#)
- [Configuring Inter-VDOM link acceleration with NP6 processors](#)

## NP6 session fast path requirements

NP6 processors can offload the following traffic and services:

- IPv4 and IPv6 traffic and NAT64 and NAT46 traffic (as well as IPv4 and IPv6 versions of the following traffic types where appropriate)
- TCP, UDP, ICMP and SCTP traffic
- IPsec VPN traffic, and offloading of IPsec encryption/decryption (including SHA2-256 and SHA2-512)
- Anomaly-based intrusion prevention, checksum offload and packet defragmentation
- SIT and IPv6 Tunnelling sessions
- Multicast traffic (including Multicast over IPsec)
- CAPWAP and wireless bridge traffic tunnel encapsulation to enable line rate wireless forwarding from FortiAP devices
- Traffic shaping and priority queuing for both shared and per IP traffic shaping. An NP6 processor has 16 million queues for traffic shaping and statistics counting.
- Syn proxying
- Inter-VDOM link traffic

Sessions that are offloaded must be fast path ready. For a session to be fast path ready it must meet the following criteria:

- Layer 2 type/length must be 0x0800 for IPv4 or 0x86dd for IPv6 (IEEE 802.1q VLAN specification is supported)
- Link aggregation between any network interfaces sharing the same network processor(s) may be used (IEEE 802.3ad specification is supported)
- Layer 3 protocol can be IPv4 or IPv6
- Layer 4 protocol can be UDP, TCP, ICMP, or SCTP
- In most cases, Layer 3 / Layer 4 header or content modification sessions that require a session helper can be offloaded.
- Local host traffic (originated by the FortiGate unit) can be offloaded
- Application layer content modification is not supported (the firewall policy that accepts the session must not include virus scanning, web filtering, DLP, application control, IPS, email filtering, SSL/SSH inspection, VoIP or ICAP)

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See [“Offloading NP pre-IPS anomaly detection” on page 1076](#).

---

If a session is not fast path ready, the FortiGate unit will not send the session key or IPsec SA key to the NP6 processor. Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key or IPsec SA key to the network processor. Session key or IPsec SA key lookups then succeed for subsequent packets from the known session or IPsec SA.

## Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for network processors' network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

## Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP6.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, VoIP control packets may not be offloaded but VoIP data packets (voice packets) may be offloaded.

## Viewing your FortiGate NP6 processor configuration

Use the following command to view the NP6 processor configuration of your FortiGate unit:

```
diagnose npu np6 port-list
```

For example output of this command for different FortiGate models, see [“FortiGate NP6 architectures” on page 1089](#).

## Increasing NP6 offloading capacity using link aggregation groups (LAGs)

NP6 processors can offload sessions received by interfaces in link aggregation (LAG) groups. You can use link aggregation groups to offload more traffic that would exceed the capacity of a single FortiGate interface. For example, if you want to offload sessions on a 30 GB link you can add three 10-GB interfaces to a LAG group and send 30 GB of traffic to the LAG group.

Just like with normal interfaces, traffic accepted by a LAG group is offloaded by the NP6 processor connected to the interfaces in the LAG group that receive the traffic to be offloaded. If all interfaces in a LAG group are connected to the same NP6 processor, traffic received by the LAG group is offloaded by that NP6 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP6 processor.

LAG groups can include interfaces connected to more than one NP6 processor. For example, adding a second NP6 processor to a LAG group effectively doubles the offloading capacity of the LAG group. Adding a third further increases capacity. Using LAG groups allows you to increase offloading capacity for incoming traffic by sharing the traffic load across multiple NP6 processors. This increase in capacity is supported by the integrated switch fabric that allows the NP6 processors to share session information.

The increase in offloading capacity may not actually be doubled by adding a second NP6 processor to a LAG group. Traffic and load conditions and other factors may limit the actual achieved offloading result.

## Configuring Inter-VDOM link acceleration with NP6 processors

FortiGate units with NP6 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

- For a FortiGate unit with two NP6 processors there are two accelerated inter-VDOM links, each with two interfaces:
  - npu0\_vlink
    - npu0\_vlink0
    - npu0\_vlink1
  - npu1\_vlink
    - npu1\_vlink0
    - npu1\_vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP6 interfaces, enter the following CLI command to display the NP6-accelerated inter-VDOM links:

```
get system interface
...

explicit-web-proxy: disable explicit-ftp-proxy: disable
mtu-override: disable wccp: disable drop-overlapped-fragment:
disable drop-fragment: disable
...
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in the pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to *System > Network > Interfaces* and edit the *npu0-vlink1* interface and set the *Virtual Domain* to *New-VDOM*. This results in an accelerated inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```

config system interface
    edit npu0-vlink1
        set vdom New-VDOM
    end

```

## Using VLANs to add more accelerated Inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to *System > Network > Interfaces* and select *Create New* to create the VLAN interface associated with the Marketing VDOM:

<b>Name</b>	Marketing-link
<b>Type</b>	VLAN
<b>Interface</b>	npu0_vlink0
<b>VLAN ID</b>	100
<b>Virtual Domain</b>	Marketing
<b>IP/Network Mask</b>	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

<b>Name</b>	Engineering-link
<b>Type</b>	VLAN
<b>Interface</b>	npu0_vlink1
<b>VLAN ID</b>	100
<b>Virtual Domain</b>	Engineering
<b>IP/Network Mask</b>	172.20.120.22/24

Or do the same from the CLI:

```

config system interface
    edit Marketing-link
        set vdom Marketing
        set ip 172.20.120.12/24
        set interface npu0_vlink0
        set vlanid 100
    next
    edit Engineering-link
        set vdom Engineering
        set ip 172.20.120.22/24
        set interface npu0_vlink1
        set vlanid 100

```

## Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP6 processor.

### **diagnose ip address list**

```
IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1
IP=10.74.1.76->10.74.1.76/255.255.252.0 index=6 devname=port2

# FortiGate NP6 architectures

Many FortiGate models can offload some types of network traffic processing from main processing resources to specialized network processors. If your network has a significant volume of traffic that is suitable for offloading, this hardware acceleration can significantly improve your network throughput.

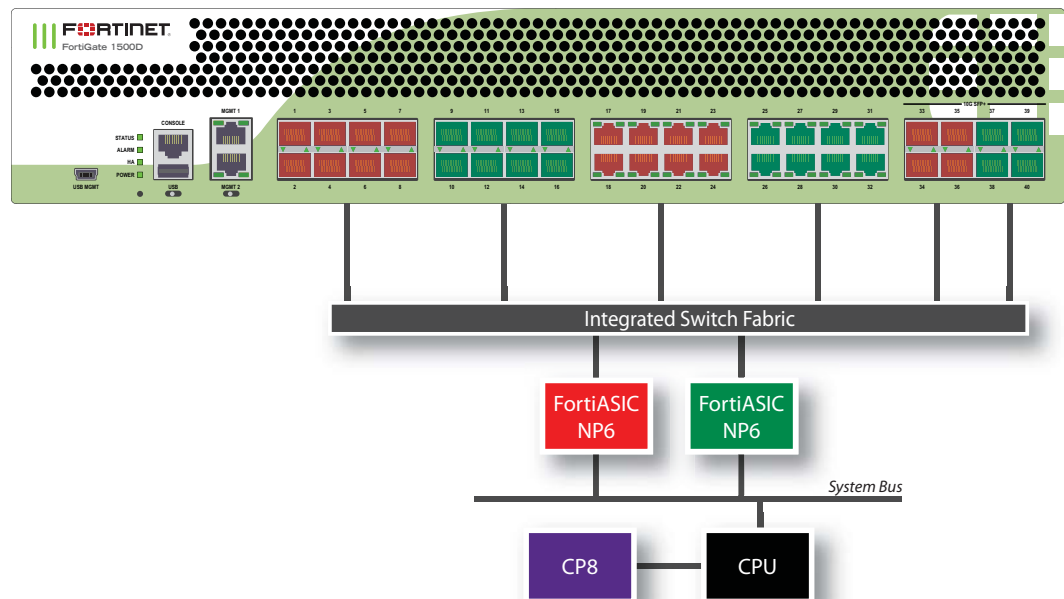

This chapter shows the fastpath architecture for the following FortiGate units:

- [FortiGate-1500D fast path architecture](#)
- [FortiGate-3700D fast path architecture](#)

## FortiGate-1500D fast path architecture

The FortiGate-1500D features two NP6 processors.

- Eight SFP 1Gb interfaces (port1-port8), eight RJ-45 Ethernet ports (port17-24) and four SFP+ 10Gb interfaces (port33-port36) share connections to the first NP6 processor.
- Eight SFP 1Gb interfaces (port9-port16), eight RJ-45 Ethernet ports (port25-32) and four SFP+ 10Gb interfaces (port37-port40) share connections to the second NP6 processor.

You can use the following command to display the FortiGate-1500D NP6 configuration. The command output shows two NP6s named NP6\_0 and NP6\_1. The output also shows the interfaces (ports) connected to each NP6.

```
diagnose npu np6 port-list
```

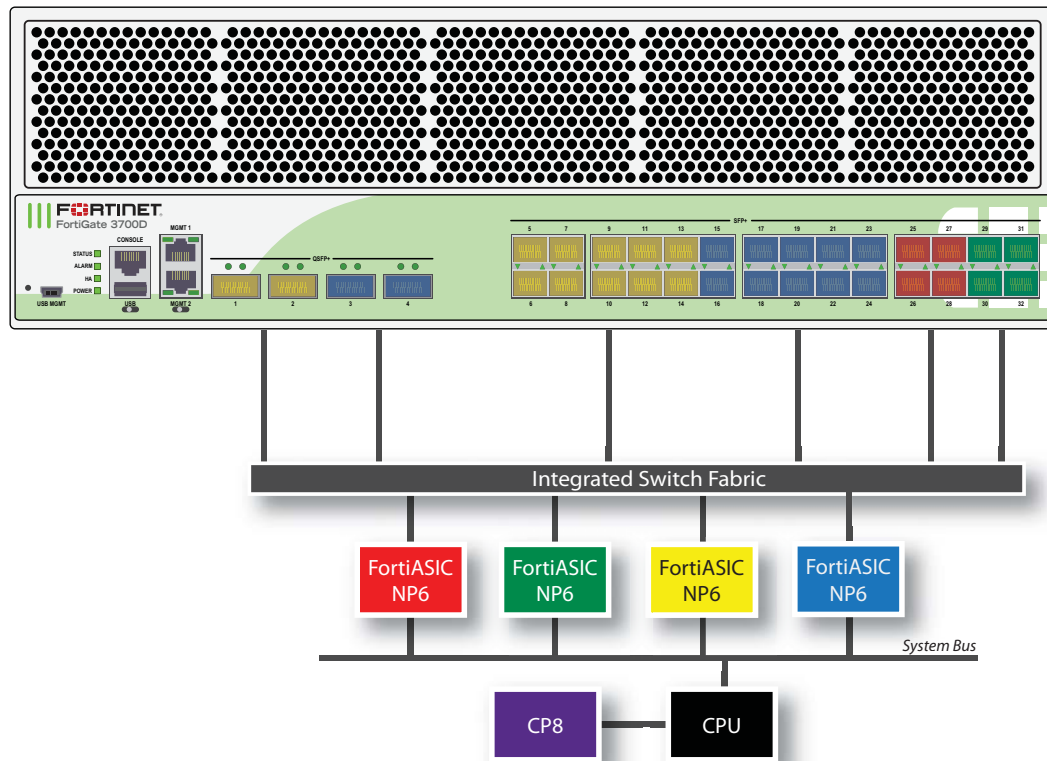

Chip	XAUI	Ports	Max Speed	Cross-chip offloading

## FortiGate-3700D fast path architecture

The FortiGate-3700D features four NP6 processors.

- Port25 through port28, SFP+ 10Gb interfaces, share connections to the first NP6 processor.
- Port29 through port32, SFP+ 10Gb interfaces, share connections to the second NP6 processor.
- Ten SFP+ 10Gb interfaces, port5 through port14, and two 40Gb QSFP interfaces, port1 and port2 share connections to the third NP6 processor.
- Ten SFP+ 10Gb interfaces, port15 through port24, and two 40Gb QSFP interfaces, port3 and port4 share connections to the fourth NP6 processor.

Ports 25 to 32 can be used for low latency offloading. As long as traffic enters and exits the FortiGate-3700D through ports connected to the same NP6 processor and using these low latency ports the traffic will be offloaded and have lower latency than other NP6 offloaded traffic. Latency is reduced by bypassing the integrated switch fabric. Specifically:

- Port25 through port28, share connections to the first NP6 processor so sessions entering one of these ports and exiting through another will experience low latency
- Port29 through port32, share connections to the second NP6 processor so sessions entering one of these ports and exiting through another will experience low latency

You can use the following command to display the FortiGate-3700D NP6 configuration. The command output shows four NP6s named NP6\_0, NP6\_1, NP6\_2, and NP6\_3. The output also shows the interfaces (ports) connected to each NP6.

```
diag npu np6 port-list

```

# NP4 Acceleration

NP4 network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP4 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP4 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP4 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP4 processor plus the network processing load is removed from the CPU. In addition, the NP4 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

Session keys (and IPsec SA keys) are stored in the memory of the NP4 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP4. The key to making this possible is the Integrated Switch Fabric (ISF) that connects the NP4s and the FortiGate unit interfaces together. The ISF allows any port connectivity. All ports and NP4s can communicate with each other over the ISF.

There are no special ingress and egress fast path requirements because traffic enters and exits on interfaces connected to the same ISF. Most FortiGate models with multiple NP4 processors connect all interfaces and NP4 processors to the same ISF (except management interfaces) so this should not ever be a problem.

There is one limitation to keep in mind; the capacity of each NP4 processor. An individual NP4 processor has a capacity of 20 Gbps (10 Gbps ingress and 10 Gbps egress). Once an NP4 processor hits its limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP4 processors. To be able to do this you need to be aware of which interfaces connect to which NP4 processors and distribute incoming traffic accordingly.

Some FortiGate units contain one NP4 processor with all interfaces connected to it and to the ISF. As a result, offloading is supported for traffic between any pair of interfaces.

Some FortiGate units include NP4Lite processors. These network processors have the same functionality and limitations as NP4 processors but with about half the performance. NP4lite processors can be found in mid-range FortiGate models such as the FortiGate-200D and 240D.

This chapter contains the following topics:

- [Viewing your FortiGate's NP4 configuration](#)
- [Configuring NP4 traffic offloading](#)
- [NP4 traffic shaping offloading](#)
- [NP4 IPsec VPN offloading](#)
- [NP4 IPsec VPN offloading configuration example](#)
- [Configuring Inter-VDOM link acceleration with NP4 processors](#)

## Viewing your FortiGate's NP4 configuration

To list the NP4 network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu np4 list
```

The output lists the interfaces that have NP4 processors. For example, for a FortiGate-5001C:

```
get hardware npu np4 list
```

ID	Model	Slot	Interface
0	On-board		port1 port2 port3 port4 fabric1 base1 npu0-vlink0 npu0-vlink1
1	On-board		port5 port6 port7 port8 fabric2 base2 npu1-vlink0 npu1-vlink1

Depending on the product, NP4 network processors may or may not be directly connected to each other on the circuit board through an EEI (Enhanced Extension Interface).

Directly connected network processors have an EEI, and can pass traffic between them without involving the FortiGate unit's main processing resources.

Indirectly connected network processors have no EEI, and cannot pass traffic between them without involving the FortiGate unit's main processing resources.

Sessions can only be offloaded if both the source and destination port are connected to the same network processor or directly (EEI) connected network processor pair.

For information about the network processors in specific FortiGate models, see [“FortiGate NP4 architectures” on page 1105](#).

### NP4lite CLI commands (disabling NP4Lite offloading)

If your FortiGate unit includes an NP4Lite processor the following commands will be available:

- Use the following command to disable or enable NP4Lite offloading. By default NP4lite offloading is enabled. If you want to disable NP4Lite offloading to diagnose a problem enter:

```
diagnose npu nplite fastpath disable
```

This command disables NP4Lite offloading until your FortiGate reboots. You can also re-enable offloading by entering the following command:

```
diagnose npu nplite fastpath enable
```

- NP4lite debug command. Use the following command to debug NP4Lite operation:

```
diagnose npl npl_debug {<parameters>}
```

## Configuring NP4 traffic offloading

Offloading traffic to a network processor requires that the FortiGate unit configuration and the traffic itself is suited to hardware acceleration. There are requirements for path the sessions and the individual packets.

### NP4 session fast path requirements

Sessions must be fast path ready. Fast path ready session characteristics are:

- Layer 2 type/length must be 0x0800 (IEEE 802.1q VLAN specification is supported); link aggregation between any network interfaces sharing the same network processor(s) may be used (IEEE 802.3ad specification is supported)
- Layer 3 protocol must be IPv4

- Layer 4 protocol must be UDP, TCP or ICMP
- Layer 3 / Layer 4 header or content modification must not require a session helper (for example, SNAT, DNAT, and TTL reduction are supported, but application layer content modification is not supported)
- Firewall policies must not include proxy-based or flow-based security features (antivirus, web filtering, email filtering, IPS, application control, or DLP)
- Origin must not be local host (the FortiGate unit)

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See [“Offloading NP pre-IPS anomaly detection” on page 1076](#).

If a session is not fast path ready, the FortiGate unit will not send the session key to the network processor(s). Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key to the network processor(s). Session key lookup then succeeds for subsequent packets from the known session.

## Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for network processors' network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

If packet requirements are not met, an individual packet will use FortiGate unit main processing resources, regardless of whether other packets in the session are offloaded to the specialized network processor(s).

In some cases, due to these requirements, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing.

For example, FTP uses two connections: a control connection and a data connection. The control connection requires a session helper, and cannot be offloaded, but the data connection does not require a session helper, and can be offloaded. Within the offloadable data session, fragmented packets will not be offloaded, but other packets will be offloaded.

Some traffic types differ from general offloading requirements, but still utilize some of the network processors' encryption and other capabilities. Exceptions include IPsec traffic and active-active high availability (HA) load balanced traffic.

## Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP4.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, FTP control packets may not be offloaded but FTP data packets (voice packets) may be offloaded.

## NP4 traffic shaping offloading

Accelerated Traffic shaping is supported with the following limitations.

- NP4 processors support policy-based traffic shaping. However, fast path traffic and traffic handled by the FortiGate CPU (slow path) are controlled separately, which means the policy setting on fast path does not consider the traffic on the slow path.
- The port based traffic policing as defined by the inbandwidth and outbandwidth CLI commands is not supported.
- DSCP configurations are supported.
- 4QoS in general is not supported.

You can also use the traffic shaping features of the FortiGate unit's main processing resources by disabling the NP4 acceleration. See [“Disabling CP offloading” on page 1070](#).

## NP4 IPsec VPN offloading

NP4 processors improve IPsec tunnel performance by offloading IPsec encryption and decryption.

Requirements for hardware accelerated IPsec encryption or decryption are a modification of general offloading requirements. Differing characteristics are:

- Origin can be local host (the FortiGate unit)
- In Phase 1 configuration, Local Gateway IP must be specified as an IP address of a network interface for a port attached to a network processor
- SA must have been received by the network processor
- in Phase 2 configuration:
  - encryption algorithm must be DES, 3DES, AES-128, AES-192, AES-256, or null
  - authentication must be MD5, SHA1, or null
  - if encryption is null, authentication must not also be null
  - if replay detection is enabled, `enc-offload-antireplay` must also be enable in the CLI

If replay detection is enabled in the Phase 2 configuration, you can enable or disable IPsec encryption and decryption offloading from the CLI. Performance varies by those CLI options and the percentage of packets requiring encryption or decryption. For details, see [“Configuring NP accelerated VPN encryption/decryption offloading” on page 1078](#).

---

To apply hardware accelerated encryption and decryption, the FortiGate unit's main processing resources must first perform Phase 1 negotiations to establish the security association (SA). The SA includes cryptographic processing instructions required by the network processor, such as which encryption algorithms must be applied to the tunnel. After ISAKMP negotiations, the FortiGate unit's main processing resources send the SA to the network processor, enabling the network processor to apply the negotiated hardware accelerated encryption or decryption to tunnel traffic.

Possible accelerated cryptographic paths are:

- IPsec decryption offload
  - Ingress ESP packet > Offloaded decryption > Decrypted packet egress (fast path)
  - Ingress ESP packet > Offloaded decryption > Decrypted packet to FortiGate unit's main processing resources

- IPsec encryption offload
  - Ingress packet > Offloaded encryption > Encrypted (ESP) packet egress (fast path)
  - Packet from FortiGate unit's main processing resources > Offloaded encryption > Encrypted (ESP) packet egress

## NP4 IPsec VPN offloading configuration example

Hardware accelerated IPsec processing, involving either partial or full offloading, can be achieved in either tunnel or interface mode IPsec configurations.

To achieve offloading for both encryption and decryption:

- In Phase 1 configuration's Advanced section, Local Gateway IP must be specified as an IP address of a network interface associated with a port attached to a network processor. (In other words, if Phase 1's Local Gateway IP is Main Interface IP, or is specified as an IP address that is not associated with a network interface associated with a port attached to a network processor, IPsec network processing is not offloaded.)
- In Phase 2 configuration's P2 Proposal section, if the checkbox "Enable replay detection" is enabled, `enc-offload-antireplay` and `dec-offload-antireplay` must be set to `enable` in the CLI.
- `offload-ipsec-host` must be set to `enable` in the CLI.

This section contains example IPsec configurations whose IPsec encryption and decryption processing is hardware accelerated by an NP4 unit contained in a FortiGate-5001B at both ends of the VPN tunnel.

Hardware accelerated IPsec VPN does not require both tunnel endpoints to have the same network processor model. However, if hardware is not symmetrical, the packet forwarding rate is limited by the slower side.

---

**Figure 183:**Example network topology for offloaded IPsec processing

**Table 54:** Example ports and IP addresses for offloaded IPsec processing

	FortiGate_1		FortiGate_2	
	Port	IP	Port	IP
<b>IPsec tunnel</b>	FortiGate-5001B port 2	3.3.3.1/24	FortiGate-5001B port 2	3.3.3.2/24
<b>Protected network</b>	FortiGate-5001B port 1	1.1.1.0/24	FortiGate-5001B port 1	2.2.2.0/24

This section includes the following topics:

- [Accelerated policy mode IPsec configuration](#)
- [Accelerated interface mode IPsec configuration](#)

## Accelerated policy mode IPsec configuration

The following steps create a hardware accelerated policy mode IPsec tunnel between two FortiGate-5001B units, each containing two NP4 processors, the first of which will be used.

### To configure hardware accelerated policy mode IPsec

1. On FortiGate\_1, go to *VPN > IPsec > Auto Key (IKE)*.
2. Configure Phase 1.
 

For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.

Select *Advanced*. In the Local Gateway IP section, select *Specify* and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate\_2's FortiGate-ASM-FB4 module port 2.
3. Configure Phase 2.
4. Select *Enable replay detection*.
5. Use the following command to enable offloading antireplay packets:
 

```
config system npu
    set enc-offload-antireplay enable
end
```

For details on encryption and decryption offloading options available in the CLI, see [“Configuring NP accelerated VPN encryption/decryption offloading”](#) on page 1078.

6. Go to *Policy > Policy > Policy*.
7. Configure a policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-5001B ports 1 and 2.
8. Go to *Router > Static > Static Route*.
9. Configure a static route to route traffic destined for FortiGate\_2's protected network to VPN IP address of FortiGate\_2's VPN gateway, 3.3.3.2, through the FortiGate-5001B port2.

You can also configure the static route using the following CLI command:

```
config router static
  edit 2
    set device "AMC-SW1/2"
    set dst 2.2.2.0 255.255.255.0
    set gateway 3.3.3.2
  end
```

10. On FortiGate\_2, go to *VPN > IPsec > Auto Key (IKE)*.

11. Configure Phase 1.

For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.

Select Advanced. In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate\_1's port2.

12. Configure Phase 2.

13. Select *Enable replay detection*.

14. Use the following command to enable offloading antireplay packets:

```
config system npu
  set enc-offload-antireplay enable
end
```

For details on encryption and decryption offloading options available in the CLI, see ["Configuring NP accelerated VPN encryption/decryption offloading" on page 1078](#).

15. Go to *Policy > Policy > Policy*.

16. Configure a policy to apply the Phase 1 IPsec tunnel you configured in step 9 to traffic between FortiGate-5001B ports 1 and 2.

17. Go to *Router > Static > Static Route*.

18. Configure a static route to route traffic destined for FortiGate\_1's protected network to VPN IP address of FortiGate\_1's VPN gateway, 3.3.3.1, through the FortiGate-5001B port2.

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "AMC-SW1/2"
    set dst 1.1.1.0 255.255.255.0
    set gateway 3.3.3.1
  end
```

19. Activate the IPsec tunnel by sending traffic between the two protected networks.

To verify tunnel activation, go to *VPN > Monitor > IPsec Monitor*.

## Accelerated interface mode IPsec configuration

The following steps create a hardware accelerated interface mode IPsec tunnel between two FortiGate units, each containing a FortiGate-ASM-FB4 module.

## To configure hardware accelerated interface mode IPsec

1. On FortiGate\_1, go to *VPN > IPsec > Auto Key (IKE)*.

2. Configure Phase 1.

For interface mode IPsec and for hardware acceleration, the following settings are required.

- Select **Advanced**.
- Enable the checkbox “Enable IPsec Interface Mode.”
- In the Local Gateway IP section, select **Specify** and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate\_2’s port 2.

3. Configure Phase 2.

4. Select *Enable replay detection*.

5. Use the following command to enable offloading antireplay packets:

```
config system npu
    set enc-offload-antireplay enable
end
```

For details on encryption and decryption offloading options available in the CLI, see [“Configuring NP accelerated VPN encryption/decryption offloading” on page 1078](#).

6. Go to *Policy > Policy > Policy*.

7. Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.

8. Go to *Router > Static > Static Route*.

9. Configure a static route to route traffic destined for FortiGate\_2’s protected network to the Phase 1 IPsec device, FGT\_1\_IPsec.

You can also configure the static route using the following CLI commands:

```
config router static
    edit 2
        set device "FGT_1_IPsec"
        set dst 2.2.2.0 255.255.255.0
    end
```

10. On FortiGate\_2, go to *VPN > IPsec > Auto Key (IKE)*.

11. Configure Phase 1.

For interface mode IPsec and for hardware acceleration, the following settings are required.

- Enable the checkbox “Enable IPsec Interface Mode.”
- In the Local Gateway IP section, select **Specify** and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate\_1’s FortiGate-5001B port 2.

12. Configure Phase 2.

13. Select *Enable replay detection*.

14. Use the following command to enable offloading antireplay packets:

```
config system npu
    set enc-offload-antireplay enable
end
```

For details on encryption and decryption offloading options available in the CLI, see [“Configuring NP accelerated VPN encryption/decryption offloading” on page 1078](#).

15. Go to *Policy > Policy > Policy*.

16. Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 9 to traffic leaving from or arriving on FortiGate-5001B port 1.

17. Go to *Router > Static > Static Route*.

**18.** Configure a static route to route traffic destined for FortiGate\_1's protected network to the Phase 1 IPsec device, FGT\_2\_IPsec.

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "FGT_2_IPsec"
    set dst 1.1.1.0 255.255.255.0
  next
end
```

**19.** Activate the IPsec tunnel by sending traffic between the two protected networks.

To verify tunnel activation, go to *VPN > Monitor > IPsec Monitor*.

## Configuring Inter-VDOM link acceleration with NP4 processors

FortiGate units with NP4 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

- For a FortiGate unit with two NP4 processors there are also two inter-VDOM links, each with two interfaces:
  - npu0-vlink
    - npu0-vlink0
    - npu0-vlink1
  - npu1-vlink
    - npu1-vlink0
    - npu1-vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP4 interfaces, enter the following CLI command (output shown for a FortiGate-5001B):

```
get hardware npu np4 list
ID      Model      Slot      Interface
0       On-board
        fabric1 base1 npu0-vlink0 npu0-vlink1
1       On-board
        port5 port6 port7 port8
        fabric2 base2 npu1-vlink0 npu1-vlink1
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in a pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to *System > Network > Interfaces* and edit the *npu0-vlink1* interface and set the *Virtual Domain* to *New-VDOM*. This results in an inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
  edit npu0-vlink1
    set vdom New-VDOM
  end
```

## Using VLANs to add more accelerated Inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to *System > Network > Interfaces* and select *Create New* to create the VLAN interface associated with the Marketing VDOM:

<b>Name</b>	Marketing-link
<b>Type</b>	VLAN
<b>Interface</b>	npu0-vlink0
<b>VLAN ID</b>	100
<b>Virtual Domain</b>	Marketing
<b>IP/Network Mask</b>	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

<b>Name</b>	Engineering-link
<b>Type</b>	VLAN
<b>Interface</b>	npu0-vlink1
<b>VLAN ID</b>	100
<b>Virtual Domain</b>	Engineering
<b>IP/Network Mask</b>	172.20.120.22/24

Or do the same from the CLI:

```
config system interface
  edit Marketing-link
    set vdom Marketing
    set ip 172.20.120.12/24
    set interface npu0-vlink0
    set vlanid 100
  next
  edit Engineering-link
    set vdom Engineering
    set ip 172.20.120.22/24
    set interface npu0-vlink1
    set vlanid 100
```

## Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP4 processor.

```
diagnose ip address list
IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1
IP=10.74.1.76->10.74.1.76/255.255.252.0 index=6 devname=port2
IP=172.20.120.12->172.20.120.12/255.255.255.0 index=55
devname=IVL-VLAN1_ROOT
```

IP=172.20.120.22->172.20.120.22/255.255.255.0 index=56  
devname=IVL-VLAN1\_VDOM1

# FortiGate NP4 architectures

This chapter shows the NP4 architecture for the following FortiGate units:

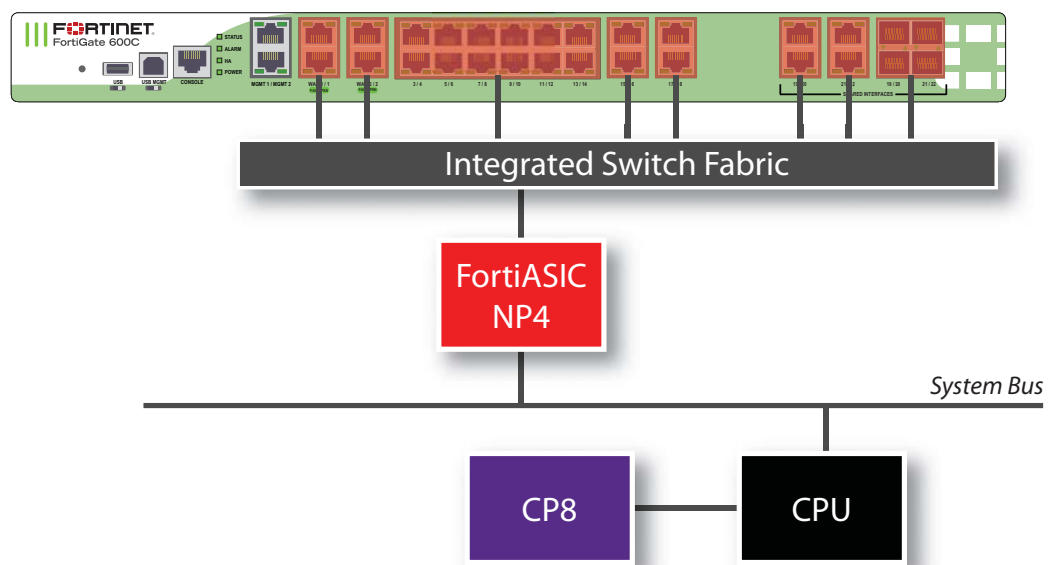

- FortiGate-600C
- FortiGate-800C
- FortiGate-1000C
- FortiGate-1240B
- FortiGate-3040B
- FortiGate-3140B
- FortiGate-3140B — load balance mode
- FortiGate-3240C
- FortiGate-3600C
- FortiGate-3950B and FortiGate-3951B
- FortiGate-5001C
- FortiGate-5001B

And includes the following reference information:

- [Setting switch-mode mapping on the ADM-XD4](#)

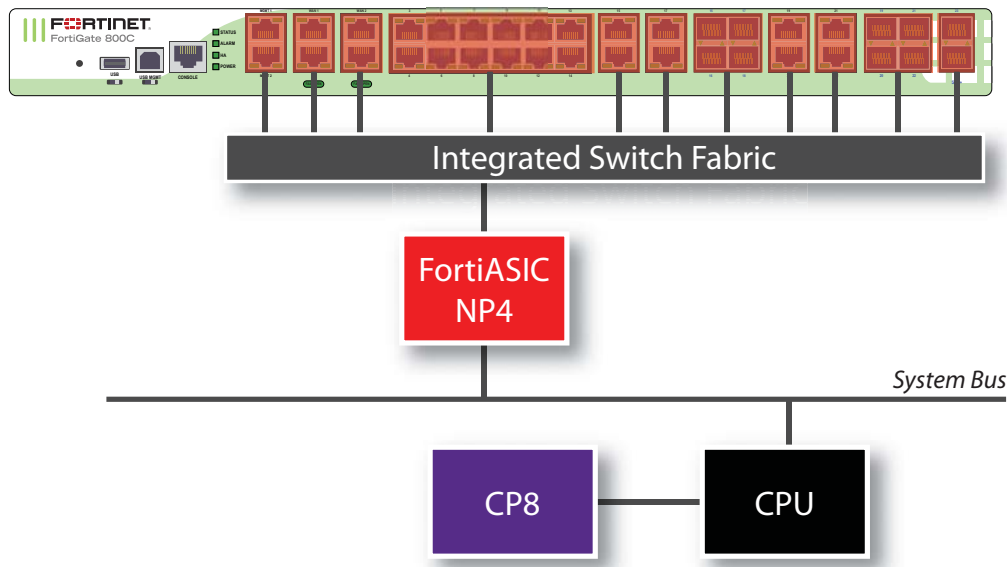

## FortiGate-600C

The FortiGate-600C features one NP4 processor. All the ports are connected to this NP4 over the Integrated Switch Fabric. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are four 1Gb SFP interface ports duplicating the port19-port22 connections.

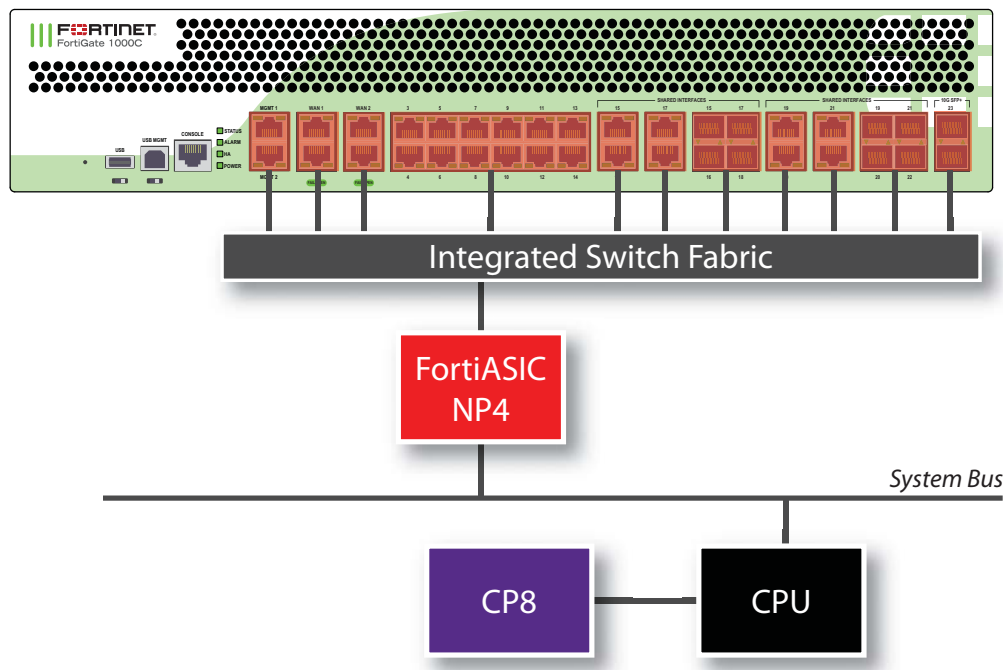

## FortiGate-800C

The FortiGate-800C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.

## FortiGate-1000C

The FortiGate-1000C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.

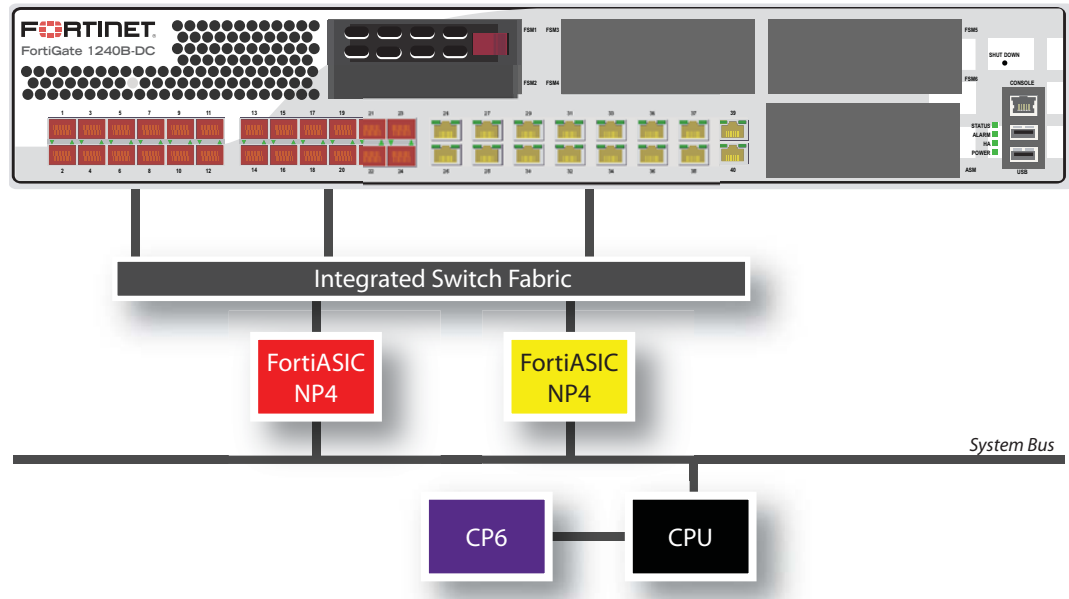

## FortiGate-1240B

The FortiGate-1240B features two NP4 processors:

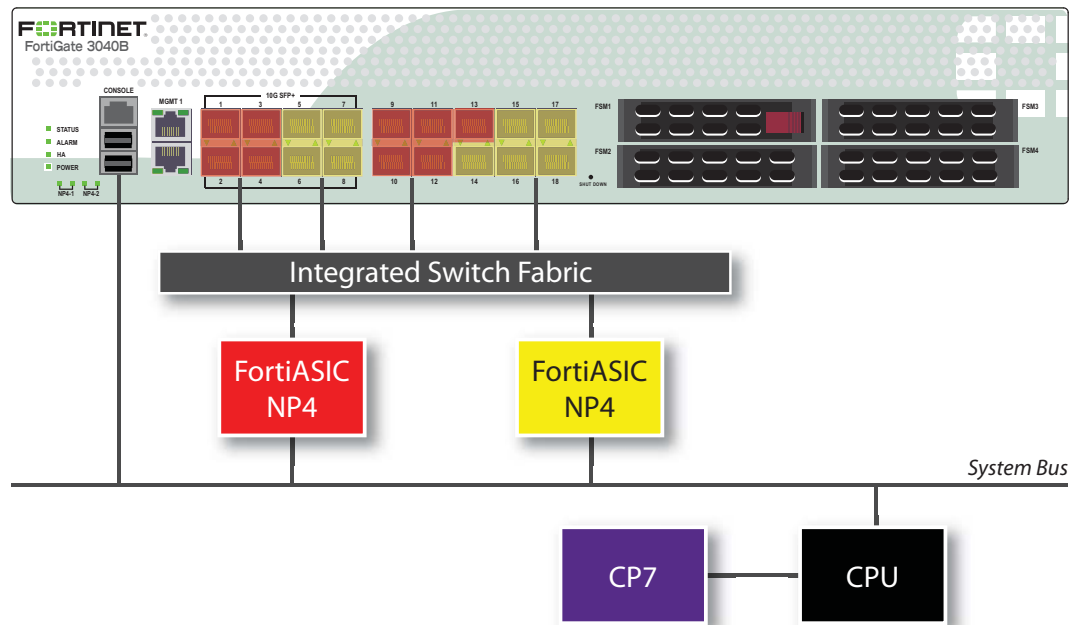

- Port1-port24 are 1Gb SFP interfaces connected to one NP4 processor.
- Port25-port40 are RJ-45 ethernet ports, connected to the other NP4 processor.

## FortiGate-3040B

The FortiGate-3040B features two NP4 processors:

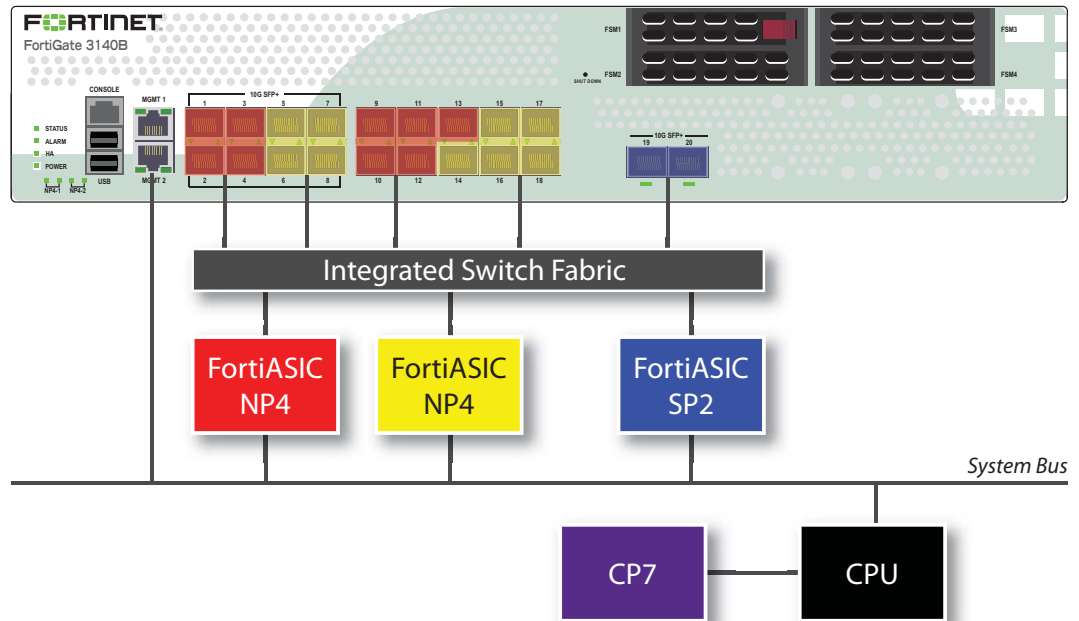

- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.

## FortiGate-3140B

The FortiGate-3140B features two NP4 processors and one SP2 processor:

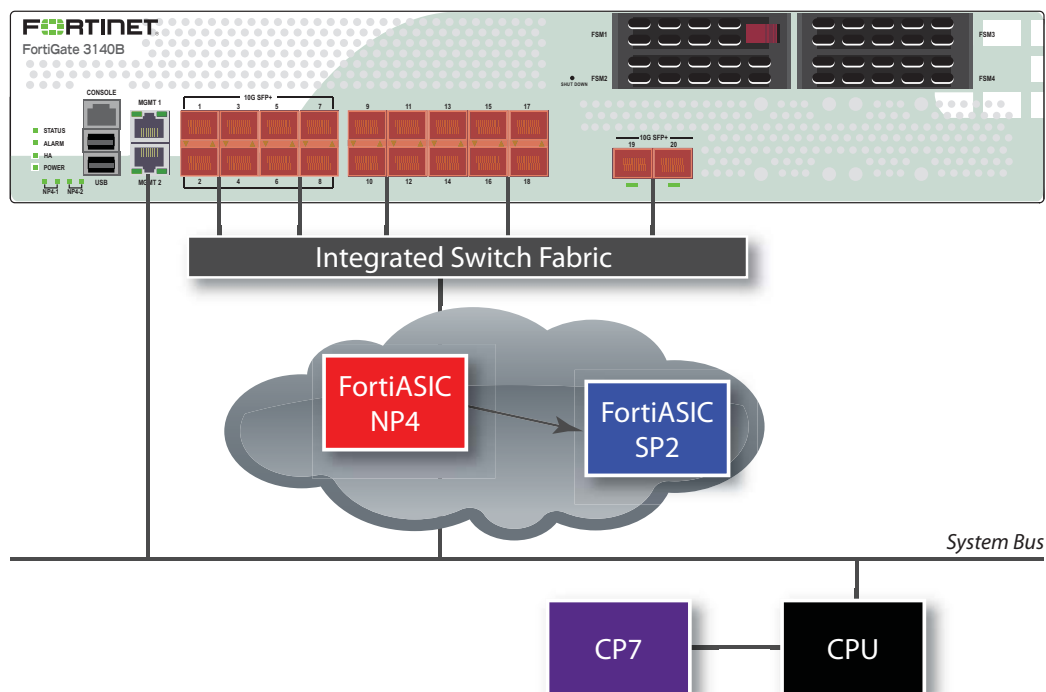

- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.
- The 10Gb interfaces, port19 and port20, share connections to the SP2 processor.

## FortiGate-3140B — load balance mode

The FortiGate-3140B load balance mode allows you increased flexibility in how you use the interfaces on the FortiGate unit. When enabled, traffic between any two interfaces (excluding management and console) is accelerated. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

To enable this feature, issue this CLI command.

```
config system global
    set sp-load-balance enable
end
```

The FortiGate unit will then restart.

To return to the default mode, issue this CLI command.

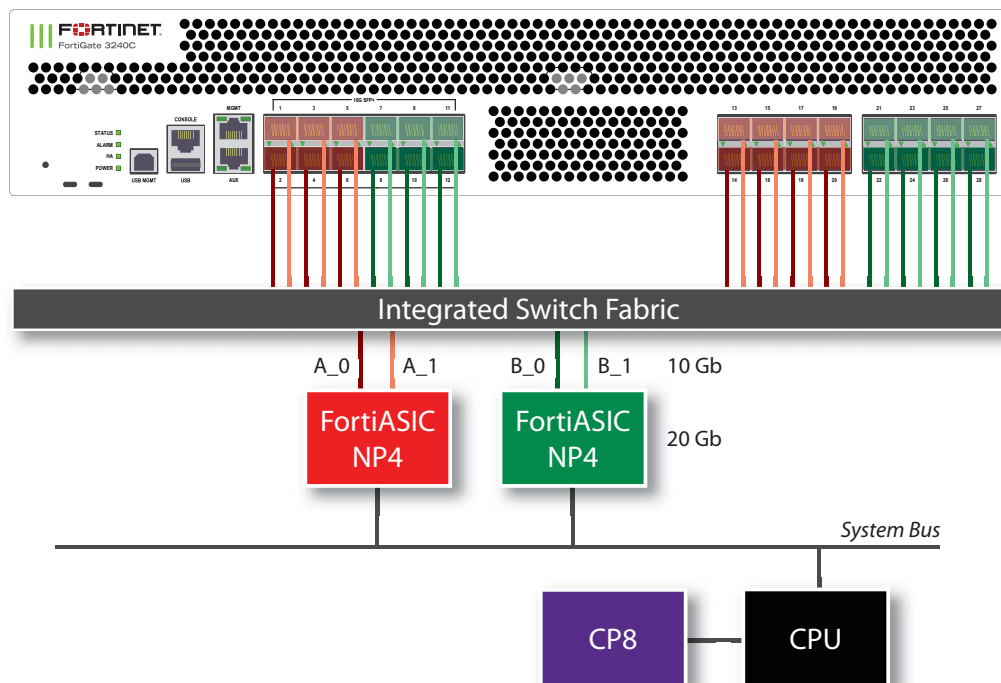

```
config system global
    set sp-load-balance disable
end
```

## FortiGate-3240C

The FortiGate-3240C features two NP4 processors:

- The 10Gb interfaces, port1 through port6, and the 1Gb interfaces, port13 through port20, share connections to one NP4 processor.
- The 10Gb interfaces, port7 through port12, and the 1Gb interfaces, port21 through port28, share connections to the other NP4 processor.

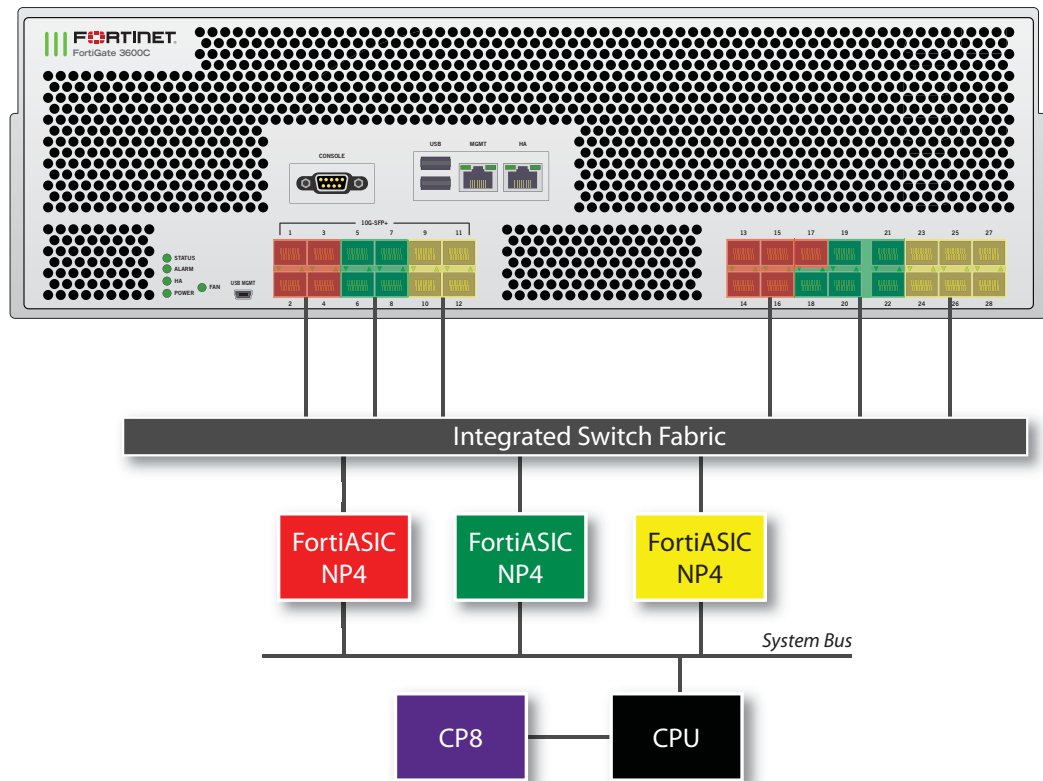

In addition to the ports being divided between the two NP4 processors, they are further divided between the two connections to each processor. Each NP4 can process 20 Gb of network traffic per second and each of two connections to each NP4 can move 10Gb of data to the processor per second, so the ideal configuration would have no more than 10 Gb of network traffic to each connection of each NP4 at any time.

## FortiGate-3600C

The FortiGate-3600C features three NP4 processors:

- The 10Gb interfaces, port1-port4, and the 1Gb interfaces, port13-port17, share connections to one NP4 processor.
- The 10Gb interfaces, port5-port8, and the 1Gb interfaces, port18-port22 share connections to the second NP4 processor.
- The 10Gb interfaces, port9-port12, and the 1Gb interfaces, port23-port28 share connections to the third NP4 processor.

### XAUI interfaces

Each NP4 processor connects to the integrated switch fabric through two XAUI interfaces: XAUI0 and XAUI1. On each NP4 processor all of the odd numbered interfaces use XAUI0 and all of the even numbered interfaces use XAUI1:

NPU1

XAUI0 = port1, port3, port13, port15, port17

XAUI1 = port2, port4, port14, port16

NPU2

XAUI0 = port5, port7, port18, port20, port22

XAUI1 = port6, port8, port19, port21

NPU3

XAU10 = port9, port11, port23, port25, port27

XAU11 = port10, port12, port24, port26, port28

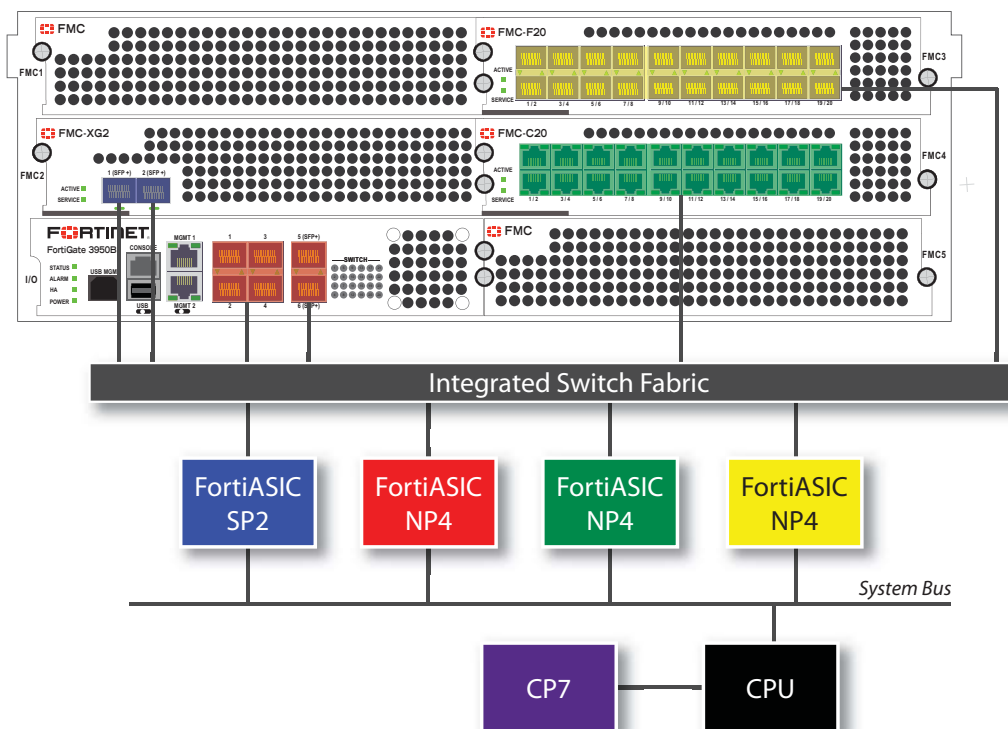

Usually you do not have to be concerned about the XAU interface mapping. However, if an NP4 interface is processing a very high amount of traffic you should distribute that traffic among both of the XAU interfaces connected to it. So if you have a very high volume of traffic flowing between two networks you should connect both networks to the same NP4 processor but to different XAU links. So between even and an add numbered FortiGate-3600C ports. For example, you could connect one network to port5 and the other network to port6. In this configuration, the second NP4 processor would handle traffic acceleration and both XAU interfaces would be processing traffic.

## FortiGate-3950B and FortiGate-3951B

The FortiGate-3950B features one NP4 processor. The 1Gb SPF interfaces, port1, port2, port3, port4, and the 10Gb SPF+ interfaces, port5, port6, share connections to one NP4 processor. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

You can add additional FMC interface modules. The diagram below shows a FortiGate-3950B with three modules installed: an FMC-XG2, an FMC-F20, and an FMC-C20.

- The FMC-XG2 has one SP2 processor. The 10Gb SPF+ interfaces, port1 and port2, share connections to the processor.
- The FMC-F20 has one NP4 processor and the twenty 1Gb SPF interfaces, port1 through port20, share connections to the NP4 processor.
- The FMC-C20 has one NP4 processor and the twenty 10/100/1000 interfaces, port1 through port20, share connections to the NP4 processor.

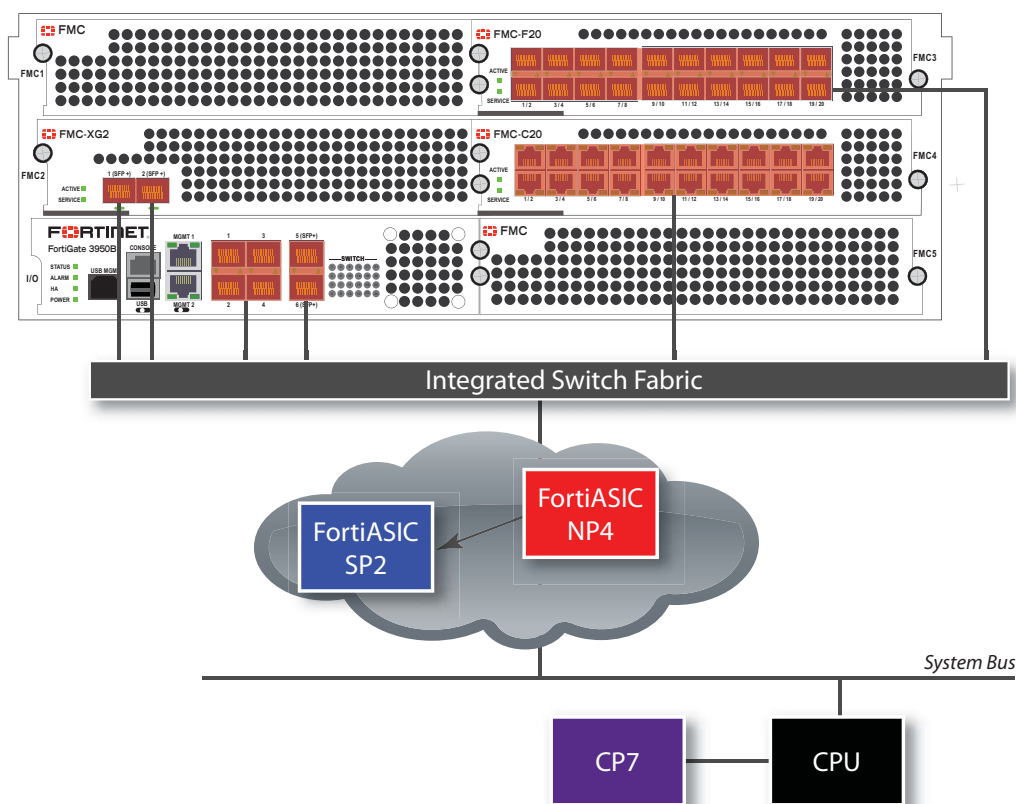

## FortiGate-3950B and FortiGate-3951B — load balance mode

Adding one or more FMC-XG2 modules to your FortiGate-3950B allows you to enable load balance mode. This feature allows you increased flexibility in how you use the interfaces on the FortiGate unit. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

When enabled, traffic between any two interfaces (excluding management and console) is accelerated whether they are the six interfaces on the FortiGate-3950B itself, or on any installed FMC modules. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

**Figure 184:**The FortiGate-3950B in load balance mode

To enable this feature, issue this CLI command.

```
config system global
    set sp-load-balance enable
end
```

The FortiGate unit will then restart.

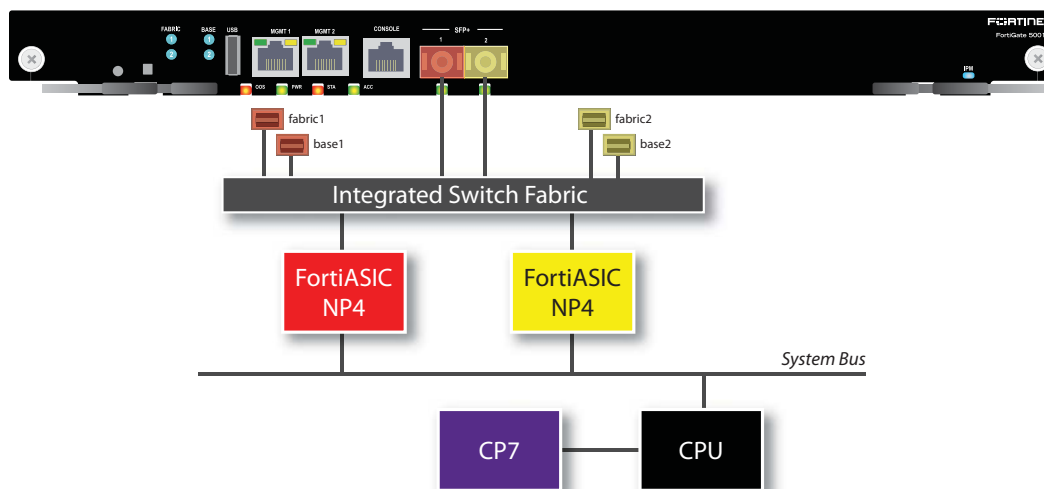

To return to the default mode, issue this CLI command.

```
config system global
    set sp-load-balance disable
end
```

## FortiGate-5001C

The FortiGate-5001C board includes two NP4 processors connected to an integrated switch fabric:

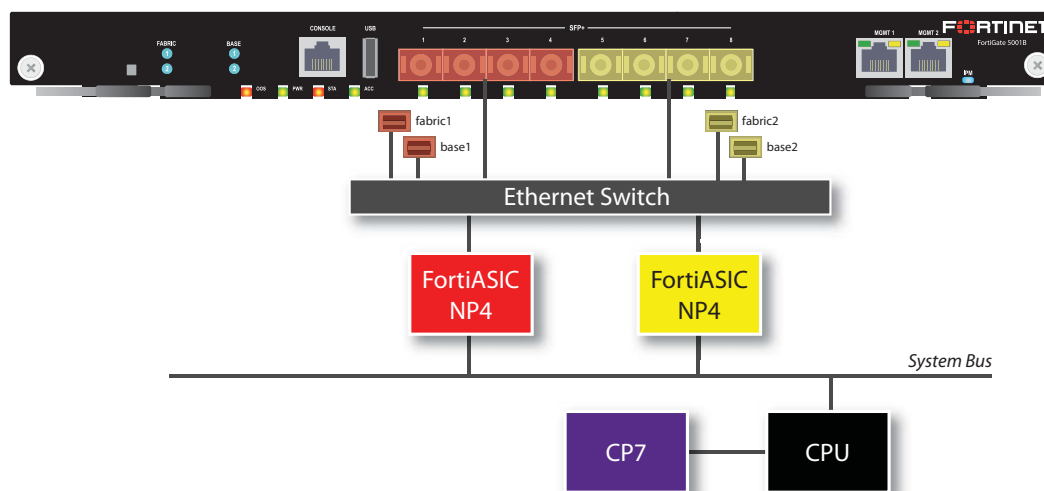

- The port1, fabric1, and base1 interfaces are connected to one NP4 processor.
- The port2, fabric2, and base2 interfaces are connected to the other NP4 processor.

## FortiGate-5001B

The FortiGate-5001B board includes two NP4 connected to an Ethernet switch. Traffic between interfaces that use the same NP4 processor experiences the highest acceleration since the FortiGate-5001B does not include an integrated switch fabric.

- The port1, port2, port3, port4, fabric1 and base1 interfaces are connected to one NP4 processor.
- The port5, port6, port7, port8, fabric2 and base2 interfaces are connected to the other NP4 processor.

For example, for maximum NP4 acceleration of traffic received on port1 the traffic must exit the FortiGate-5001B board on port2, port3, port4, or fabric1. Also, for maximum acceleration of traffic received on port5 the traffic must exit the FortiGate-5001B board on port6, port7, port8, or fabric2.

## Setting switch-mode mapping on the ADM-XD4

The ADM-XD4 SP has four 10Gb/s ports, but the NP4 processor it contains has only two 10Gb/s ports. The external ports you use are important to optimize the SP for your application.

**Figure 185:**ADM-XD4 mapping mode

Ports 1 and 3 share one NP4 processor and ports 2 and 4 share the other. Performance ports sharing the same NP4 processor is far better than when forcing network data to move between NP4 processors by using one port from each, for example ports 1 and 2 or ports 3 and 4.

# Chapter 9 High Availability for FortiOS

## 5.0

This FortiOS Handbook chapter contains the following sections:

[Solving the High Availability problem](#) describes the high availability problem and introduces the FortiOS solutions described in this document (FGCP, VRRP, and standalone session synchronization).

[An introduction to the FGCP](#) introduces the FGCP clustering protocol and many of its features and terminology.

[Configuring and connecting HA clusters](#) describes configuring HA clusters and contains HA clustering configuration examples.

[Virtual clusters](#) describes configuring HA virtual clusters and contains virtual clustering configuration examples.

[Full mesh HA](#) describes configuring FortiGate Full mesh HA and contains a full mesh HA configuration example.

[Operating a cluster](#) describes how to operate a cluster and includes detailed information about how various FortiGate systems operate differently in a cluster.

[HA and failover protection](#) describes in detail how FortiGate HA device failover, link failover, and session failover work.

[HA and load balancing](#) describes in detail how FortiGate HA active-active load balancing load balances sessions.

[HA with FortiGate-VM and third-party products](#) describes how FortiGate units interact with third-party products.

[VRRP](#) describes FortiOS support of the Virtual Router Redundancy Protocol (VRRP) and its use for high availability.

[FortiGate Session Life Support Protocol \(FGSP\)](#) describes the FortiGate standalone session synchronization feature and its use for high availability.

[Configuring FRUP](#) describes how to set up a FortiGate Redundant UTM Protocol (FRUP) cluster consisting of two FortiGate-100D units.

-

# Solving the High Availability problem

The basic high availability (HA) problem for TCP/IP networks and security gateways is keeping network traffic flowing. Uninterrupted traffic flow is a critical component for online systems and media because critical business processes quickly come to a halt when the network is down.

The security gateway is a crucial component of most networks since all traffic passes through it. A standalone network security gateway is a single point of failure that is vulnerable to any number of software or hardware problems that could compromise the device and bring all traffic on the network to a halt.

A common solution to the high availability problem is to eliminate the security gateway as single point of failure by introducing redundancy. With two or more redundant security gateways, if one fails, the remaining one or more gateways keep the traffic flowing. FortiOS provides four redundancy solutions: industry standard VRRP as well as three proprietary solutions: FortiGate Cluster Protocol (FGCP) high availability, FortiGate Session Life Support Protocol (FGSP) high availability, and the Fortinet Redundant UTM protocol (FRUP) high availability.

You can combine more than one high availability solution into a single configuration. A common reason for doing this could be to add VRRP to an FGCP or FGSP configuration.

A strong and flexible High availability solution is required for many mission-critical firewall and UTM applications. Each FortiOS high availability solution can be fine tuned to fit into many different network scenarios.

## FortiGate Cluster Protocol (FGCP)

FGCP HA provides a solution for two key requirements of critical enterprise networking components: enhanced reliability and increased performance. Enhanced reliability is achieved through device failover protection, link failover protection, and remote link failover protection. Also contributing to enhanced reliability is session failover protection for most IPv4 and IPv6 sessions including TCP, UDP, ICMP, IPsec VPN, and NAT sessions. Increased performance is achieved through active-active HA load balancing. Extended FGCP features include full mesh HA and virtual clustering. You can also fine tune the performance of the FGCP to change how a cluster forms and shares information among cluster units and how the cluster responds to failures.

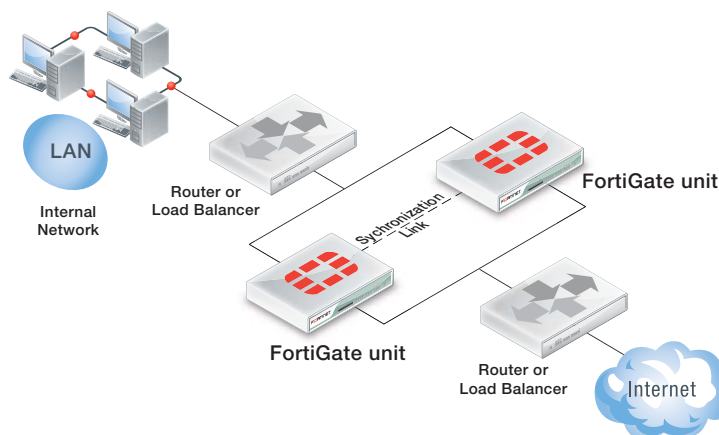

When configured onto your network an FGCP cluster appears to be a single FortiGate unit operating in NAT/Route or Transparent mode and configuration synchronization allows you to configure a cluster in the same way as a standalone FortiGate unit. If a failover occurs, the cluster recovers quickly and automatically and also sends administrator notifications so that the problem that caused the failure can be corrected and any failed equipment restored.

The FGCP is compatible with most network environments and most networking equipment. While initial configuration is relatively quick and easy, a large number of tools and configuration options are available to fine tune the cluster for most situations.

## FortiGate Session Life Support Protocol (FGSP)

In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two identical FortiGate units can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute sessions among the FortiGate units and the FGSP performs session synchronization of IPv4 and IPv6 TCP, UDP, ICMP, expectation, and NAT sessions to keep the session tables of both FortiGate units synchronized.

If one of the FortiGate units fails, session failover occurs and active sessions fail over to the unit that is still operating. This failover occurs without any loss of data. As well, the external load balancers or routers detect the failover and re-distribute all sessions to the unit that is still operating.

Load balancing and session failover is done by external routers or load balancers and not by the FGSP. The FortiGate units just perform session synchronization which allows session failover to occur without packet loss.

The FGSP also includes configuration synchronization, allowing you to make configuration changes once for both FortiGate units instead of requiring duplicate configuration changes on each unit. Settings that identify the FortiGate unit to the network, for example, interface IP addresses and BGP neighbor settings, are not synchronized so each FortiGate unit maintains its identity on the network. These settings must be configured separately for each FortiGate unit.

In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. However, the FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions.

## VRRP

FortiGate units can function as master or backup Virtual Router Redundancy Protocol (VRRP) routers and can be quickly and easily integrated into a network that has already deployed VRRP. A FortiGate unit can be integrated into a VRRP group with any third-party VRRP devices and VRRP can provide redundancy between multiple FortiGate units.

In a VRRP configuration, when a FortiGate unit operating as the master unit fails, a backup unit takes its place and continues processing network traffic. If the backup unit is a FortiGate unit, the network continues to benefit from FortiOS security features. If the backup unit is a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate unit is back on line. You can include different FortiGate models in the same VRRP group.

FortiOS supports VRRP between two or more FortiGate units and between FortiGate units and third-party routers that support VRRP. Using VRRP you can assign VRRP routers as master or backup routers. The master router processes traffic and the backup routers monitor the master router and can begin forwarding traffic if the master fails. Similar to the FGCP you can configuration VRRP between multiple FortiGate units to provide redundancy. You can also create a VRRP group with a FortiGate units and any routers that support VRRP.

In a VRRP configuration that consists of one FortiGate unit and one router, normally the FortiGate unit would be the master and all traffic would be processed by the FortiGate unit. If the FortiGate unit fails, all traffic switches to the router. Network connectivity is maintained even though FortiGate security features will be unavailable until the FortiGate unit can is back on line.

## Fortinet redundant UTM protocol (FRUP)

An extension to the FGCP combines switching HA and firewall HA into a single unified design. This feature is available on the FortiGate-100D and will be expanded to other models in future releases.

A FRUP setup consists of 2 (and only 2) identical FortiGate-100D units. The setup supports dual redundant HA links between the units for sharing session and configuration data.

FRUP requires redundant external routers where:

- One FortiGate unit has a primary connection to one of the routers and a backup connection to the other.
- The other FortiGate unit has the opposite configuration.

See “Configuring FRUP” on page 1380 for an example configuration.

# An introduction to the FGCP

A FortiGate HA cluster consists of two to four FortiGate units configured for HA operation. Each FortiGate unit in a cluster is called a cluster unit. All cluster units must be the same FortiGate model with the same FortiOS firmware build installed. All cluster units must also have the same hardware configuration (for example, the same AMC modules installed in the same slots, the same number of hard disks and so on) and be running in the same operating mode (NAT/Route mode or Transparent mode).

You can create an FGCP cluster of up to four FortiGate units.

---

In addition the cluster units must be able to communicate with each other through their heartbeat interfaces. This heartbeat communication is required for the cluster to be created and to continue operating. Without it, the cluster acts like a collection of standalone FortiGate units.

On startup, after configuring the cluster units with the same HA configuration and connecting their heartbeat interfaces, the cluster units use the FortiGate Clustering Protocol (FGCP) to find other FortiGate units configured for HA operation and to negotiate to create a cluster. During cluster operation, the FGCP shares communication and synchronization information among the cluster units over the heartbeat interface link. This communication and synchronization is called the FGCP heartbeat or the HA heartbeat. Often, this is shortened to just heartbeat.

The cluster uses the FGCP to select the primary unit, and to provide device, link and session failover. The FGCP also manages the two HA modes; active-passive (failover HA) and active-active (load balancing HA).

This chapter describes.

## About the FGCP

FortiGate HA is implemented by configuring two or more FortiGate units to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate unit, processing network traffic and providing normal security services such as firewalling, security services, Unified Threat Management (UTM) and VPN services.

**Figure 186:** HA cluster installed between an internal network and the Internet

Inside the cluster the individual FortiGate units are called cluster units. These cluster units share state and configuration information. If one cluster unit fails, the other units in the cluster automatically replace that unit, taking over the work that the failed unit was doing. After the failure, the cluster continues to process network traffic and provide normal FortiGate services with virtually no interruption.

Every FortiGate cluster contains one primary unit (also called the master unit) and one or more subordinate units (also called slave or backup units). The primary unit controls how the cluster operates. The role that the subordinate units play depends on the mode in which the cluster operates: (Active-Passive (AP) or Active-Active (AA) (see [“Active-passive HA \(failover protection\)”](#) on page 1128 and [“Active-active HA \(load balancing and failover protection\)”](#) on page 1129).

The ability of an HA cluster to continue providing firewall services after a failure is called failover. FGCP failover means that your network does not have to rely on one FortiGate unit to continue functioning. You can install additional units and form an HA cluster.

A second HA feature, called load balancing, can be used to increase performance. A cluster of FortiGate units can increase overall network performance by sharing the load of processing network traffic and providing security services. The cluster appears to your network to be a single device, adding increased performance without changing your network configuration.

Virtual clustering extends HA features to provide failover protection and load balancing for Virtual Domains (VDOMs). See [“Virtual clusters”](#) on page 1217.

FortiGate models that support redundant interfaces can be configured to support full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster. For details about full mesh HA, see [“Full mesh HA”](#) on page 1239.

## FGCP failover protection

The FGCP provides IP/MAC takeover for failover protection by assigning virtual MAC addresses to the primary cluster unit and then sending gratuitous ARP packets from the primary unit interfaces to reprogram the network.

Failover times can be less than a second under optimal conditions. You can fine tune failover performance for your network by adjusting cluster status checking timers, routing table update timers, and wait timers.

An HA cluster fails over if the primary unit fails (a device failure) or experiences a link failure. The cluster can detect link failures for connections to the primary unit using port monitoring and for connections between downstream network components using remote IP monitoring. To compensate for a link failover, the cluster maintains active links to keep traffic flowing between high-priority networks. Port and remote IP monitoring can be fine tuned without disrupting cluster operation.

## Session Failover

FGCP session failover maintains TCP, SIP and IPsec VPN sessions after a failure. You can also configure session failover to maintain UDP and ICMP sessions. Session failover does not failover multicast, or SSL VPN sessions. Session failover may not be required for all networks because many TCP/IP, UDP, and ICMP protocols can resume sessions on their own. Supporting session failover adds extra overhead to cluster operations and can be disabled to improve cluster performance if it is not required.

## Load Balancing

Active-active HA load balances resource-intensive virus scanning, web filtering, intrusion protection, Application Control, email filtering and Data Leak Prevention operations among all cluster units to provide better performance than a standalone FortiGate unit. If network traffic consists of mainly TCP sessions, the FGCP can also load balance all TCP sessions to improve TCP performance in some network configurations. You can also load balance UDP sessions. You can use accelerated FortiGate interfaces to also accelerate HA load balancing and HA load balancing schedules can be adjusted to optimize performance for the traffic mix on your network. Weighted load balancing can be used to control the relative amount of sessions processed by each cluster unit.

## Virtual Clustering

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGate units operating with multiple VDOMS enabled. Not only does virtual clustering provide failover protection for a multiple VDOM configuration, but a virtual cluster can load balance traffic between the cluster units. Load balancing with virtual clustering is quite efficient and load balances all traffic (not just UTM and TCP traffic). Its possible to fine tune virtual clustering load balancing in real time to actively optimize load sharing between the cluster units without affecting the smooth operation of the cluster.

## Full Mesh HA

High availability improves the reliability of a network by replacing a single point of failure (a single FortiGate unit) with a cluster that can maintain network traffic if one of the cluster units fails. However, in a normal cluster configuration, single points of failure remain. Full mesh HA removes these single points of failure by allowing you to connect redundant switches to each cluster interface. Full mesh HA is achieved by configuring 802.3ad aggregate or redundant interfaces on the FortiGate unit and connecting redundant switches to these interfaces. Configuration is a relatively simple extension of the normal aggregate/redundant interface and HA configurations.

## Cluster Management

FortiOS HA provides a wide range of cluster management features:

- Automatic continuous configuration synchronization. You can get a cluster up and running almost as quickly as a standalone FortiGate unit by performing a few basic steps to configure HA settings and minimal network settings on each cluster unit. When the cluster is operating you can configure FortiGate features such as firewalling, content inspection, and VPN in the same way as for a standalone FortiGate unit. All configuration changes (even complex changes such as switching to multiple VDOM mode or from NAT/Route to Transparent mode) are synchronized among all cluster units.
- Firmware upgrades/downgrades. Upgrading or downgrading cluster firmware is similar to upgrading or downgrading standalone FortiGate firmware. The Firmware is uploaded once to the primary unit and the cluster automatically upgrades or downgrades all cluster units in one operation with minimal or no service interruption.
- Individual cluster unit management. In some cases you may want to manage individual cluster units. You can do so from cluster CLI by navigating to each cluster unit. You can also use the reserved management interface feature to give each cluster unit its own IP address and default route. You can use the reserved management interfaces and IP addresses to connect to the GUI and CLI of each cluster unit and configure an SNMP server to poll each cluster unit.
- Removing and adding cluster units. In one simple step any unit (even the primary unit) can be removed from a cluster and given a new IP address. The cluster keeps operating as it was; the transition happening without interrupting cluster operation. A new unit can also be added to an operating cluster without disrupting network traffic. All you have to do is connect the new unit and change its HA configuration to match the cluster's. The cluster automatically finds and adds the unit and synchronizes its configuration with the cluster.
- Debug and diagnose commands. An extensive range of debug and diagnose commands can be used to report on HA operation and find and fix problems.
- Logging and reporting. All cluster units can be configured to record all log messages. These messages can be stored on the individual cluster units or sent to a FortiAnalyzer unit. You can view all cluster unit log messages by logging into any cluster unit.
- FortiManager support. FortiManager understands FortiOS HA and automatically recognizes when you add a FortiOS cluster to the FortiManager configuration.

## Synchronizing the configuration (and settings that are not synchronized)

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. This means that in most cases you only have to make a configuration change once to have it synchronized to all cluster units.

Some configuration settings are not synchronized to support some aspects of FortiGate operation. The following settings are not synchronized among cluster units:

- The FortiGate unit host name. Allows you to identify cluster units.
- HA override ([“HA override” on page 1138](#)).
- HA device priority ([“Primary unit selection and device priority” on page 1136](#)).
- Virtual cluster 1 and Virtual cluster 2 device priorities ([“Virtual clustering and load balancing or VDOM partitioning” on page 1218](#))
- The HA priority (`ha-priority`) setting for a ping server or dead gateway detection configuration ([“Remote link failover” on page 1325](#)).
- The system interface settings of the FortiGate interface that becomes the HA reserved management interface ([“Managing individual cluster units using a reserved management interface” on page 1254](#)).
- The default route for the reserved management interface, set using the `ha-mgt-interface-gateway` option of the `config system ha` command ([“Managing individual cluster units using a reserved management interface” on page 1254](#)).
- The dynamic weighted load balancing thresholds and high and low watermarks ([“Dynamically optimizing weighted load balancing according to how busy cluster units are” on page 1350](#)).

## Configuring FortiGate units for FGCP HA operation

Each FortiGate unit in the cluster must have the same HA configuration. Once the cluster is connected, you can configure it in the same way as you would configure a standalone FortiGate unit. The following procedures set the HA mode to active-passive and set the HA password to `HA_pass`.

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP you will not be able to configure HA.

---

### To configure a FortiGate unit for HA operation - web-based manager

1. Power on the FortiGate unit to be configured.
2. Log into the web-based manager.
3. On the Dashboard *System Information* dashboard widget, beside *Host Name* select *Change*.
4. Enter a new Host Name for this FortiGate unit.

Changing the host name makes it easier to identify individual cluster units when the cluster is operating.

5. Go to *System > Config > HA* and change the following settings:

<b>Mode</b>	Active-Passive
<b>Group Name</b>	Example_cluster
<b>Password</b>	HA_pass The password must be the same for all FortiGate units in the cluster.

You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

6. Select *OK*.

The FortiGate unit negotiates to establish an HA cluster. When you select *OK* you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all ARP table entries). You may be able to delete the ARP table of your management PC from a command prompt using a command similar to `arp -d`.

7. Power off the FortiGate unit.
8. Repeat this procedure for all of the FortiGate units in the cluster.

Once all of the units are configured, continue with [“Connecting a FortiGate HA cluster” on page 1127](#).

### To configure a FortiGate unit for HA operation - CLI

1. Power on the FortiGate unit to be configured.
2. Log into the CLI.
3. Enter the following command to change the FortiGate unit host name.

```
config system global
    set hostname Example1_host
end
```

Changing the host name makes it easier to identify individual cluster units when the cluster is operating.

4. Enter the following command to enable HA:

```
config system ha
    set mode active-passive
    set group-name Example_cluster
    set password HA_pass
end
```

You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

5. Power off the FortiGate unit.

6. Repeat this procedure for all of the FortiGate units in the cluster.

Once all of the units are configured, continue with [“Connecting a FortiGate HA cluster”](#).

## Connecting a FortiGate HA cluster

Use the following procedure to connect a cluster. Connect the cluster units to each other and to your network. You must connect all matching interfaces in the cluster to the same switch, then connect these interfaces to their networks using the same switch.

Although you can use hubs, Fortinet recommends using switches for all cluster connections for the best performance.

Connecting an HA cluster to your network temporarily interrupts communications on the network because new physical connections are being made to route traffic through the cluster. Also, starting the cluster interrupts network traffic until the individual cluster units are functioning and the cluster completes negotiation. Cluster negotiation is automatic and normally takes just a few seconds. During system startup and negotiation all network traffic is dropped.

This section describes how to connect the cluster shown in [Figure 187 on page 1127](#) that consists of two FortiGate-100D units to be connected between the Internet and a head office internal network. The wan1 interfaces of the FortiGate unit connect the cluster to the Internet and the internal interfaces connect the cluster to the internal network. The ha1 and ha2 interfaces are used for redundant HA heartbeat links.

**Figure 187:**Example cluster connections

### To connect a FortiGate HA cluster

1. Connect the WAN1 interfaces of each cluster unit to a switch connected to the Internet.
2. Connect the Port1 interfaces of each cluster unit to a switch connected to the internal network.
3. Connect the HA1 interfaces of the cluster units together. You can use a crossover Ethernet cable or a regular Ethernet cable. (You can also connect the interfaces using Ethernet cables and a switch.)
4. Connect the HA2 interfaces of the cluster units together. You can use a crossover Ethernet cable or a regular Ethernet cable. (You can also connect the interfaces using Ethernet cables and a switch.)

5. Power on both of the FortiGate units.

As the cluster units start, they negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally just takes a few seconds.

At least one heartbeat interface should be connected together for the cluster to operate.

Do not use a switch port for the HA heartbeat traffic. This configuration is not supported.

You could use one switch to connect all four heartbeat interfaces. However, this is not recommended because if the switch fails both heartbeat interfaces will become disconnected.

For more information about heartbeat interfaces, see [“HA heartbeat and communication between cluster units” on page 1293](#).

6. You can now configure the cluster as if it is a single FortiGate unit.

## Active-passive and active-active HA

The first decision to make when configuring FortiGate HA is whether to choose active-passive or active-active HA mode. To configure the HA mode, go to *System > Config > HA* and set Mode to *Active-Passive* or *Active-Active*.

From the CLI enter the following command to set the HA mode to active-passive:

```
config system ha
    set mode a-p
end
```

To form a cluster, all cluster units must be set to the same mode. You can also change the mode after the cluster is up and running. Changing the mode of a functioning cluster causes a slight delay while the cluster renegotiates to operate in the new mode and possibly select a new primary unit.

### Active-passive HA (failover protection)

An active-passive (A-P) HA cluster provides hot standby failover protection. An active-passive cluster consists of a primary unit that processes communication sessions, and one or more subordinate units. The subordinate units are connected to the network and to the primary unit but do not process communication sessions. Instead, the subordinate units run in a standby state. In this standby state, the configuration of the subordinate units is synchronized with the configuration of the primary unit and the subordinate units monitor the status of the primary unit.

Active-passive HA provides transparent device failover among cluster units. If a cluster unit fails, another immediately take its place. See [“Device failover” on page 1292](#).

Active-passive HA also provides transparent link failover among cluster units. If a cluster unit interface fails or is disconnected, this cluster unit updates the link state database and the cluster negotiates and may select a new primary unit. See [“Link failover \(port monitoring or interface monitoring\)” on page 1319](#) for more information.

If session failover (also called session pickup) is enabled, active-passive HA provides session failover for some communication sessions. See [“Session failover \(session pick-up\)” on page 1330](#) for information about session failover and its limitations.

The following example shows how to configure a FortiGate unit for active-passive HA operation. You would enter the exact same commands on every FortiGate unit in the cluster.

```
config system ha
    set mode a-p
    set group-name myname
    set password HApass
end
```

## Active-active HA (load balancing and failover protection)

Active-active (A-A) HA load balances resource-intensive content inspection processing among all cluster units. Content inspection processing applies protocol recognition, virus scanning, IPS, web filtering, email filtering, data leak prevention (DLP), application control, and VoIP content scanning and protection to HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, NNTP, SIP, SIMPLE, and SCCP sessions accepted by security policies. By load balancing this resource-intensive processing among all cluster units, an active-active HA cluster may provide better content inspection performance than a standalone FortiGate unit. Other features enabled in security policies such as Endpoint security, traffic shaping, user authentication, and device identification have no effect active-active load balancing.

Normally, sessions that don't include content inspection are not load balanced and are processed by the primary unit. You can configure active-active HA to load balance additional sessions. For more information see [“Load balancing UTM sessions, TCP sessions, and UDP sessions” on page 1347](#).

An active-active HA cluster consists of a primary unit that receives all communication sessions and load balances them among the primary unit and all of the subordinate units. In an active-active cluster the subordinate units are also considered active since they also process content processing sessions. In all other ways active-active HA operates the same as active-passive HA.

The following example shows how to configure a FortiGate unit for active-active HA operation. You would enter the exact same commands on every FortiGate unit in the cluster.

```
config system ha
    set mode a-a
    set group-name myname
    set password HApass
end
```

## Identifying the cluster and cluster units

You can use the cluster group name, group id, and password to identify a cluster and distinguish one cluster from another. If you have more than one cluster on the same network, each cluster must have a different group name, group id, and password.

### Group name

Use the group name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units.

The default group name is *FGT-HA*. The group name appears on the FortiGate dashboard of a functioning cluster as the *Cluster Name*.

To change the group name from the web-based manager go to *Config > System > HA* and change the *Group Name*.

Enter the following CLI command to change the group name to *Cluster\_name*:

```
config system ha
    set group-name Cluster_name
end
```

## Password

Use the password to identify the cluster. You should always change the password when configuring a cluster. The password must be the same for all FortiGate units before they can form a cluster. When the cluster is operating you can change the password, if required. Two clusters on the same network cannot have the same password.

To change the password from the web-based manager go to *Config > System > HA* and change the *Password*.

Enter the following CLI command to change the password to *ha\_pwd*:

```
config system ha
    set password ha_pwd
end
```

## Group ID

Similar to the group name, the group ID also identifies the cluster. In most cases you do not have to change the group ID. However, you should change the group ID if you have more than one cluster on the same network. All members of the HA cluster must have the same group ID. The group ID is a number from 0 to 255.

Changing the group ID changes the cluster virtual MAC address. See [“Cluster virtual MAC addresses” on page 1300](#).

Enter the following CLI command to change the group ID to 10:

```
config system ha
    set group-id 10
end
```

## Device failover, link failover, and session failover

The FGCP provides transparent device and link failover. You can also enable session pickup to provide session failover. A failover can be caused by a hardware failure, a software failure, or something as simple as a network cable being disconnected causing a link failover. When a failover occurs, the cluster detects and recognizes the failure and takes steps to respond so that the network can continue to operate without interruption. The internal operation of the cluster changes, but network components outside of the cluster notice little or no change.

If a failover occurs, the cluster also records log messages about the event and can be configured to send log messages to a syslog server and to a FortiAnalyzer unit. The cluster can also send SNMP traps and alert email messages. These alerts can notify network administrators of the failover and may contain information that the network administrators can use to find and fix the problem that caused the failure.

For a complete description of device failover, link failover, and session failover, how clusters support these types of failover, and how FortiGate HA clusters compensate for a failure to maintain network traffic flow see [“HA and failover protection” on page 1290](#).

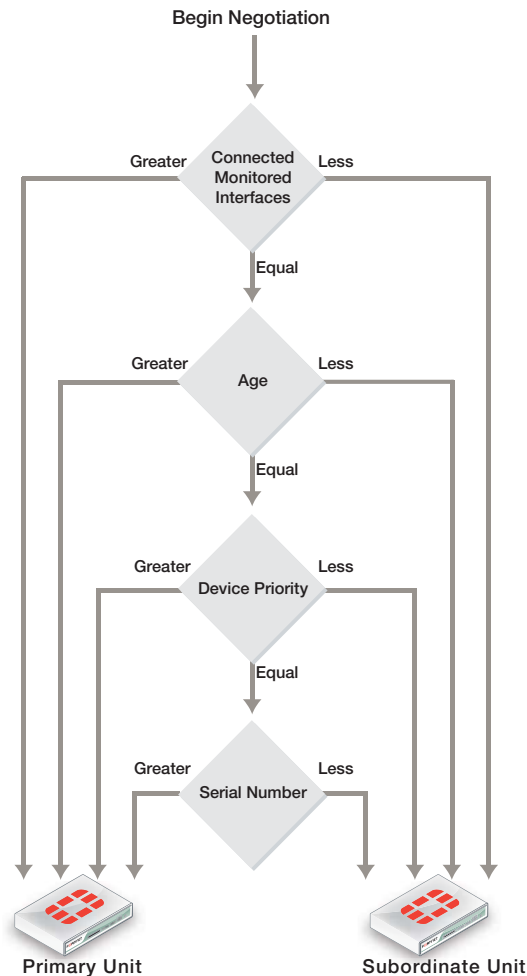

## Primary unit selection

Once FortiGate units recognize that they can form a cluster, the cluster units negotiate to select a primary unit. Primary unit selection occurs automatically based on the criteria shown in [Figure 188](#). After the cluster selects the primary unit, all of the remaining cluster units become subordinate units.

Negotiation and primary unit selection also takes place if a primary unit fails (device failover) or if a monitored interface fails or is disconnected (link failover). During a device or link failover, the cluster renegotiates to select a new primary unit also using the criteria shown in [Figure 188](#).

**Figure 188:** Selecting the primary unit

For many basic HA configurations primary unit selection simply selects the cluster unit with the highest serial number to become the primary unit. A basic HA configuration involves setting the HA mode to active-passive or active-active and configuring the cluster group name and password. Using this configuration, the cluster unit with the highest serial number becomes the primary unit because primary unit selection disregards connected monitored interfaces (because interface monitoring is not configured), the age of the cluster units would usually always be the same, and all units would have the same device priority.

Using the serial number is a convenient way to differentiate cluster units; so basing primary unit selection on the serial number is predictable and easy to understand and interpret. Also the cluster unit with the highest serial number would usually be the newest FortiGate unit with the most recent hardware version. In many cases you may not need active control over primary unit selection, so basic primary unit selection based on serial number is sufficient.

In some situations you may want have control over which cluster unit becomes the primary unit. You can control primary unit selection by setting the device priority of one cluster unit to be higher than the device priority of all other cluster units. If you change one or more device priorities, during negotiation, the cluster unit with the highest device priority becomes the primary unit. As shown in [Figure 188](#) the FGCP selects the primary unit based on device priority before serial number. For more information about how to use device priorities, see [“Primary unit selection and device priority” on page 1136](#).

The only other way that you can influence primary unit selection is by configuring interface monitoring (also called port monitoring). Using interface monitoring you can make sure that cluster units with failed or disconnected monitored interfaces cannot become the primary unit. See [“Primary unit selection and monitored interfaces” on page 1132](#).

Finally, the age of a cluster unit is determined by a number of operating factors. Normally the age of all cluster units is the same so normally age has no effect on primary unit selection. Age does affect primary unit selection after a monitored interface failure. For more information about age, see [“Primary unit selection and age” on page 1133](#).

This section describes:

- [Primary unit selection and monitored interfaces](#)
- [Primary unit selection and age](#)
- [Primary unit selection and device priority](#)
- [Primary unit selection and the FortiGate unit serial number](#)
- [Points to remember about primary unit selection](#)

## Primary unit selection and monitored interfaces

If you have configured interface monitoring the cluster unit with the highest number of monitored interfaces that are connected to networks becomes the primary unit. Put another way, the cluster unit with the highest number of failed or disconnected monitored interfaces cannot become the primary unit.

Normally, when a cluster starts up, all monitored interfaces of all cluster units are connected and functioning normally. So monitored interfaces do not usually affect primary unit selection when the cluster first starts.

A cluster always renegotiates when a monitored interface fails or is disconnected (called link failover). A cluster also always renegotiates when a failed or disconnected monitored interface is restored.

If a primary unit monitored interface fails or is disconnected, the cluster renegotiates and if this is the only failed or disconnected monitored interface the cluster selects a new primary unit.

If a subordinate unit monitored interface fails or is disconnected, the cluster also renegotiates but will not necessarily select a new primary unit. However, the subordinate unit with the failed or disconnected monitored interface cannot become the primary unit.

Multiple monitored interfaces can fail or become disconnected on more than one cluster unit. Each time a monitored interface is disconnected or fails, the cluster negotiates to select the cluster unit with the most connected and operating monitored interfaces to become the primary unit. In fact, the intent of the link failover feature is just this, to make sure that the primary unit is always the cluster unit with the most connected and operating monitored interfaces. For information about monitored interfaces and link failover see [“Link failover \(port monitoring or interface monitoring\)” on page 1319](#).

## Primary unit selection and age

The cluster unit with the highest age value becomes the primary unit. The age of a cluster unit is the amount of time since a monitored interface failed or is disconnected. Age is also reset when a cluster unit starts (boots up). So, when all cluster units start up at about the same time, they all have the same age. Age does not affect primary unit selection when all cluster units start up at the same time. Age also takes precedence over priority for primary unit selection.

If a link failure of a monitored interface occurs, the age value for the cluster unit that experiences the link failure is reset. So, the cluster unit that experienced the link failure also has a lower age value than the other cluster units. This reduced age does not effect primary unit selection because the number of link failures takes precedence over the age.

If the failed monitored interface is restored the cluster unit that had the failed monitored interface cannot become the primary unit because its age is still lower than the age of the other cluster units.

In most cases, the way that age is handled by the cluster reduces the number of times the cluster selects a new primary unit, which results in a more stable cluster since selecting a new primary unit has the potential to disrupt traffic.

### Cluster age difference margin (grace period)

In any cluster, some of the cluster units may take longer to start up than others. This startup time difference can happen as a result of a number of issues and does not affect the normal operation of the cluster. To make sure that cluster units that start slower can still become primary units, by default the FGCP ignores age differences of up to 5 minutes (300 seconds).

In most cases, during normal operation this age difference margin or grace period helps clusters function as expected. However, the age difference margin can result in some unexpected behavior in some cases:

- During a cluster firmware upgrade with `uninterruptible-upgrade` enabled (the default configuration) the cluster should not select a new primary unit after the firmware of all cluster units has been updated. But since the age difference of the cluster units is most likely less than 300 seconds, age is not used to affect primary unit selection and the cluster may select a new primary unit. See [“Upgrading cluster firmware” on page 1274](#) for more information.
- During failover testing where cluster units are failed over repeatedly the age difference between the cluster units will most likely be less than 5 minutes. During normal operation, if a failover occurs, when the failed unit rejoins the cluster its age will be very different from the age of the still operating cluster units so the cluster will not select a new primary unit. However, if a unit fails and is restored in a very short time the age difference may be less than 5 minutes. As a result the cluster may select a new primary unit during some failover testing scenarios.

### Changing the cluster age difference margin

You can change the cluster age difference margin using the following command:

```
config system ha
    set ha-uptime-diff-margin 60
end
```

This command sets the cluster age difference margin to 60 seconds (1 minute). The age difference margin range 1 to 65535 seconds. The default is 300 seconds.

You may want to reduce the margin if during failover testing you don't want to wait the default age difference margin of 5 minutes. You may also want to reduce the margin to allow uninterruptible upgrades to work. See [“Upgrading cluster firmware” on page 1274](#).

You may want to increase the age margin if cluster unit startup time differences are larger than 5 minutes.

## Displaying cluster unit age differences

You can use the CLI command `diagnose sys ha dump-by all-vcluster` to display the age difference of the units in a cluster. This command also displays information about a number of HA-related parameters for each cluster unit. You can enter the command from the primary unit CLI or you can enter the command from a subordinate unit after using `execute ha manage` to log into a subordinate unit CLI. The information displayed by the command is relative to the unit that you enter the command from.

For example, a cluster of two FortiGate-5001C units with no changes to the default HA configuration except to enable port monitoring for port1. Entering the `diagnose sys ha dump-by all-vcluster` command from the primary unit CLI displays information similar to the following:

```
diagnose sys ha dump-by all-vcluster
      HA information.
vcluster id=1, nentry=2, state=work, digest=4.a5.60.11.cf.d4...
ventry idx=0,id=1,FG-5KC3E13800084,prio=128,-50,claimed=0,
      override=0,flag=1,time=0,mon=0
      mondev=port1,50
ventry idx=1,id=1,FG-5KC3E13800046,prio=128,-50,claimed=0,
      override=0,flag=0,time=-98,mon=0
```

The command displays one `ventry` line for each cluster unit. The first `ventry` in the example contains information for the cluster unit that you are logged into (usually the primary unit). The other `ventry` lines contain information for the other units in the cluster (in the example there is only one other cluster unit). The command also includes a `mondev` entry that displays the interface monitoring configuration.

The `time` field is always 0 for the unit that you are logged into. The `time` field for the other cluster unit is the age difference between the unit that you are logged into and the other cluster unit. The age difference is in the form seconds/10.

In the example, the age of the primary unit is 12.9 seconds more than the age of the subordinate unit. The age difference is less than 5 minutes (less than 300 seconds) so age has no affect on primary unit selection. The cluster selected the unit with the highest serial number to be the primary unit.

If you use `execute ha manage 1` to log into the subordinate unit CLI and enter `diagnose sys ha dump 1` you get results similar to the following:

```
diagnose sys ha dump-by all-vcluster
      HA information.
vcluster id=1, nentry=2, state=standby, digest=4.a5.60.11.cf.d4...
ventry idx=1,id=1,FG-5KC3E13800046,prio=128,-50,claimed=0,
      override=0,flag=1,time=0,mon=0
      mondev=port1,50
ventry idx=0,id=1,FG-5KC3E13800084,prio=128,-50,claimed=1,
      override=0,flag=0,time=98,mon=0
```

The `time` for the primary unit is 98, indicating that age of the subordinate unit age is 9.8 seconds higher than the primary unit age.

If port1 (the monitored interface) of the primary unit is disconnected, the cluster renegotiates and the former subordinate unit becomes the primary unit. When you log into the new primary unit CLI and enter `diagnose sys ha dump-by all-vcluster` you could get results similar to the following:

```
diagnose sys ha dump-by all-vcluster
      HA information.
vcluster id=1, nventry=2, state=work, digest=3.f8.d1.63.4d.d2...
ventry idx=0,id=1,FG-5KC3E13800046,prio=128,0,claimed=0,
      override=0,flag=1,time=0,mon=0
      mondev=port1,50
ventry idx=1,id=1,FG-5KC3E13800084,prio=128,-50,claimed=0,
      override=0,flag=0,time=1362,mon=0
```

The command results show that the age of the new primary unit is 136.2 seconds higher than the age of the new subordinate unit.

If port1 of the former primary unit is reconnected the cluster will once again make this the primary unit because the age difference will still be less than 300 seconds. When you log into the primary unit CLI and enter `diagnose sys ha dump-by all-vcluster` you get results similar to the following:

```
diagnose sys ha dump-by all-vcluster
      HA information.
vcluster id=1, nventry=2, state=work, digest=4.a5.60.11.cf.d4...
ventry idx=0,id=1,FG-5KC3E13800084,prio=128,0,claimed=0,
      override=0,flag=1,time=0,mon=0
      mondev=port1,50
ventry idx=1,id=1,FG-5KC3E13800046,prio=128,0,claimed=0,
      override=0,flag=0,time=-1362,mon=0
```

## Resetting the age of all cluster units

In some cases, age differences among cluster units can result in the wrong cluster unit or the wrong virtual cluster becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units when it rejoins the cluster. Since age takes precedence over priority, the priority of this cluster unit will not be a factor in primary unit selection.

This problem also affects virtual cluster VDOM partitioning in a similar way. After a reboot of one of the units in a virtual cluster configuration, traffic for all VDOMs could continue to be processed by the cluster unit that did not reboot. This can happen because the age of both virtual clusters on the unit that did not reboot is greater than the age of both virtual clusters on the unit that rebooted.

One way to resolve this issue is to reboot all of the cluster units at the same time so that the age of all of the cluster units is reset. However, rebooting cluster units may interrupt or at least slow down traffic. If you would rather not reboot all of the cluster units you can instead use the following command to reset the age of individual cluster units.

```
diagnose sys ha reset-uptime
```

This command resets the age of a unit back to zero so that if no other unit in the cluster was reset at the same time, it will now have the lowest age. You would use this command to reset the age of the cluster unit that is currently the primary unit. Since it will have the lowest age, the other unit in the cluster will have the highest age and can then become the primary unit.

The `diagnose sys ha reset-uptime` command should only be used as a temporary solution. The command resets the HA age internally and does not affect the up time displayed for cluster units using the `diagnose sys ha dump-by all-vcluster` command or the up time displayed on the Dashboard or cluster members list. To make sure the actual up time for cluster units is the same as the HA age you should reboot the cluster units during a maintenance window.

## Primary unit selection and device priority

A cluster unit with the highest device priority becomes the primary unit when the cluster starts up or renegotiates. By default, the device priority for all cluster units is 128. You can change the device priority to control which FortiGate unit becomes the primary unit during cluster negotiation. All other factors that influence primary unit selection either cannot be configured (age and serial number) or are synchronized among all cluster units (interface monitoring). You can set a different device priority for each cluster unit. During negotiation, if all monitored interfaces are connected, and all cluster units enter the cluster at the same time (or have the same age), the cluster with the highest device priority becomes the primary unit.

A higher device priority does not affect primary unit selection for a cluster unit with the most failed monitored interfaces or with an age that is higher than all other cluster units because failed monitored interfaces and age are used to select a primary unit before device priority.

Increasing the device priority of a cluster unit does not always guarantee that this cluster unit will become the primary unit. During cluster operation, an event that may affect primary unit selection may not always result in the cluster renegotiating. For example, when a unit joins a functioning cluster, the cluster will not renegotiate. So if a unit with a higher device priority joins a cluster the new unit becomes a subordinate unit until the cluster renegotiates.

Enabling the `override` HA CLI keyword makes changes in device priority more effective by causing the cluster to negotiate more often to make sure that the primary unit is always the unit with the highest device priority. For more information about `override`, see [“HA override” on page 1138](#).

## Controlling primary unit selection by changing the device priority

You set a different device priority for each cluster unit to control the order in which cluster units become the primary unit when the primary unit fails.

To change the device priority from the web-based manager go to *Config > System > HA* and change the *Device Priority*.

Enter the following CLI command to change the device priority to 200:

```
config system ha
    set priority 200
end
```

The device priority is not synchronized among cluster units. In a functioning cluster you can change the device priority of any unit in the cluster. Whenever you change the device priority of a cluster unit, when the cluster negotiates, the unit with the highest device priority becomes the primary unit.

The following example shows how to change the device priority of a subordinate unit to 255 so that this subordinate unit becomes the primary unit. You can change the device priority of a subordinate unit by going to *Config > System > HA* and selecting the Edit icon for the subordinate unit. Or from the CLI you can use the `execute ha manage 0` command to connect to the highest priority subordinate unit. After you enter the following commands the cluster renegotiates and selects a new primary unit.

```
execute ha manage 1
config system ha
    set priority 255
end
```

If you have three units in a cluster you can set the device priorities as shown in [Table 55](#). When the cluster starts up, cluster unit A becomes the primary unit because it has the highest device priority. If unit A fails, unit B becomes the primary unit because unit B has a higher device priority than unit C.

**Table 55:** Example device priorities for a cluster of three FortiGate units

Cluster unit	Device priority
A	200
B	100
C	50

When configuring HA you do not have to change the device priority of any of the cluster units. If all cluster units have the same device priority, when the cluster first starts up the FGCP negotiates to select the cluster unit with the highest serial number to be the primary unit. Clusters also function normally if all units have the same device priority.

You can change the device priority if you want to control the roles that individual units play in the cluster. For example, if you want the same unit to always become the primary unit, set this unit device priority higher than the device priority of other cluster units. Also, if you want a cluster unit to always become a subordinate unit, set this cluster unit device priority lower than the device priority of other cluster units.

If you have a cluster of three units you can set a different priority for each unit to control which unit becomes the primary unit when all three cluster units are functioning and which will be the primary unit when two cluster units are functioning.

The device priority range is 0 to 255. The default device priority is 128.

If you are configuring a virtual cluster, if you have added virtual domains to both virtual clusters, you can set the device priority that the cluster unit has in virtual cluster 1 and virtual cluster 2. If a FortiGate unit has different device priorities in virtual cluster 1 and virtual cluster 2, the FortiGate unit may be the primary unit in one virtual cluster and the subordinate unit in the other. For more information, see [“Virtual clustering and load balancing or VDOM partitioning” on page 1218](#).

## Primary unit selection and the FortiGate unit serial number

The cluster unit with the highest serial number is more likely to become the primary unit. When first configuring FortiGate units to be added to a cluster, if you do not change the device priority of any cluster unit, then the cluster unit with the highest serial number always becomes the primary unit.

Age does take precedence over serial number, so if a cluster unit takes longer to join a cluster for some reason (for example if one cluster unit is powered on after the others), that cluster unit will not become the primary unit because the other units have been in the cluster longer.

Device priority and failed monitored interfaces also take precedence over serial number. A higher device priority means a higher priority. So if you set the device priority of one unit higher or if a monitored interface fails, the cluster will not use the FortiGate serial number to select the primary unit.

## Points to remember about primary unit selection

Some points to remember about primary unit selection:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored interfaces > Age > Device Priority > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered if a cluster unit fails or if a monitored interface fails.
- If the HA age difference is more than 5 minutes (300 seconds), the cluster unit that is operating longer becomes the primary unit.
- If HA age difference is less than 5 minutes (300 seconds), the device priority and FortiGate serial number selects the cluster unit to become the primary unit.
- Every time a monitored interface fails the HA age of the cluster unit is reset to 0.
- Every time a cluster unit restarts the HA age of the cluster unit is reset to 0.

## HA override

The HA `override` CLI keyword is disabled by default. When `override` is disabled a cluster may not always renegotiate when an event occurs that affects primary unit selection. For example, when `override` is disabled a cluster will not renegotiate when you change a cluster unit device priority or when you add a new cluster unit to a cluster. This is true even if the unit added to the cluster has a higher device priority than any other unit in the cluster. Also, when `override` is disabled a cluster does not negotiate if the new unit added to the cluster has a failed or disconnected monitored interface.

For a virtual cluster configuration, `override` is enabled by default for both virtual clusters when you enable virtual cluster 2. For more information, see [“Virtual clustering and HA override” on page 1218](#).

In most cases you should keep `override` disabled to reduce how often the cluster negotiates. Frequent negotiations may cause frequent traffic interruptions.

However, if you want to make sure that the same cluster unit always operates as the primary unit and if you are less concerned about frequent cluster negotiation you can set its device priority higher than other cluster units and enable `override`.

To enable `override`, connect to each cluster unit CLI (using the `execute ha manage` command) and use the `config system ha` CLI command to enable `override`.

For `override` to be effective, you must also set the device priority highest on the cluster unit that you want to always be the primary unit. To increase the device priority, from the CLI use the `config system ha` command and increase the value of the `priority` keyword to a number higher than the default priority of 128.

You can also increase the device priority from the web-based manager by going to *System > Config > HA*. To increase the device priority of the primary unit select edit for the primary or subordinate unit and set the *Device Priority* to a number higher than 128.

The `override` setting and device priority value are not synchronized to all cluster units. You must enable `override` and adjust device priority manually and separately for each cluster unit.

---

With `override` enabled, the primary unit with the highest device priority will always become the primary unit. Whenever an event occurs that may affect primary unit selection, the cluster negotiates. For example, when `override` is enabled a cluster renegotiates when you change the device priority of any cluster unit or when you add a new unit to a cluster.

This section also describes:

- [Override and primary unit selection](#)
- [Controlling primary unit selection using device priority and `override`](#)
- [Points to remember about primary unit selection when `override` is enabled](#)
- [Configuration changes can be lost if `override` is enabled](#)
- [Override and disconnecting a unit from a cluster](#)

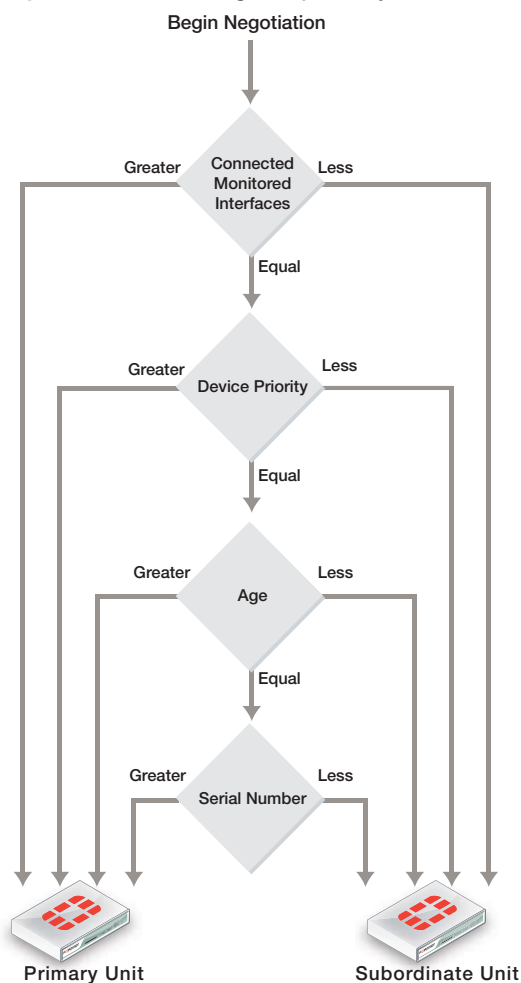

## Override and primary unit selection

Enabling `override` changes the order of primary unit selection. As shown in [Figure 189](#) if `override` is enabled, primary unit selection considers device priority before age and serial number. This means that if you set the device priority higher on one cluster unit, with `override` enabled this cluster unit becomes the primary unit even if its age and serial number are lower than other cluster units.

Similar to when `override` is disabled, when `override` is enabled primary unit selection checks for connected monitored interfaces first. So if interface monitoring is enabled, the cluster unit with the most disconnected monitored interfaces cannot become the primary unit, even if the unit has the highest device priority.

If all monitored interfaces are connected (or interface monitoring is not enabled) and the device priority of all cluster units is the same then age and serial number affect primary unit selection.

**Figure 189:** Selecting the primary unit with override enabled

## Controlling primary unit selection using device priority and override

To configure one cluster unit to always become the primary unit you should set its device priority to be higher than the device priorities of the other cluster units and you should enable `override` on all cluster units.

Using this configuration, when the cluster is operating normally the primary unit is always the unit with the highest device priority. If the primary unit fails the cluster renegotiates to select another cluster unit to be the primary unit. If the failed primary unit recovers, starts up again and rejoins the cluster, because `override` is enabled, the cluster renegotiates. Because the restarted primary unit has the highest device priority it once again becomes the primary unit.

In the same situation with `override` disabled, because the age of the failed primary unit is lower than the age of the other cluster units, when the failed primary unit rejoins the cluster it does not become the primary unit. Instead, even though the failed primary unit may have the highest device priority it becomes a subordinate unit because its age is lower than the age of all the other cluster units.

## Points to remember about primary unit selection when override is enabled

Some points to remember about primary unit selection when `override` is enabled:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored Interfaces > Device Priority > Age > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered whenever an event occurs which may affect primary unit selection. For example negotiation occurs, when you change the device priority, when you add a new unit to a cluster, if a cluster unit fails, or if a monitored interface fails.
- Device priority is considered before age. Otherwise age is handled the same when `override` is enabled.

## Configuration changes can be lost if override is enabled

In some cases, when `override` is enabled and you make configuration changes to an HA cluster these changes can be lost. For example, consider the following sequence:

1. A cluster of two FortiGate units is operating with `override` enabled.
  - FGT-A: Primary unit with device priority 200 and with `override` enabled
  - FGT-B: Subordinate unit with device priority 100 and with `override` disabled
  - If both units are operating, FGT-A always becomes the primary unit because FGT-A has the highest device priority.
2. FGT-A fails and FGT-B becomes the new primary unit.
3. The administrator makes configuration changes to the cluster.

The configuration changes are made to FGT-B because FGT-B is operating as the primary unit. These configuration changes are not synchronized to FGT-A because FGT-A is not operating.
4. FGT-A is restored and starts up again.
5. The cluster renegotiates and FGT-A becomes the new primary unit.
6. The cluster recognizes that the configurations of FGT-A and FGT-B are not the same.
7. The configuration of FGT-A is synchronized to FGT-B.

The configuration is always synchronized from the primary unit to the subordinate units.
8. The cluster is now operating with the same configuration as FGT-A. The configuration changes made to FGT-B have been lost.

## The solution

When `override` is enabled, you can prevent configuration changes from being lost by doing the following:

- Verify that all cluster units are operating before making configuration changes (from the web-based manager go to *System > Config > HA* to view the cluster members list or from the FortiOS CLI enter `get system ha status`).
- Make sure the device priority of the primary unit is set higher than the device priorities of all other cluster units before making configuration changes.
- Disable `override` either permanently or until all configuration changes have been made and synchronized to all cluster units.

## Override and disconnecting a unit from a cluster

A similar scenario to that described in “[Configuration changes can be lost if override is enabled](#)” may occur when `override` is enabled and you use the Disconnect from Cluster option from the web-based manager or the `execute ha disconnect` command from the CLI to disconnect a cluster unit from a cluster.

Configuration changes made to the cluster can be lost when you reconnect the disconnected unit to the cluster. You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. Otherwise, when the disconnected unit joins the cluster, if `override` is enabled, the cluster renegotiates and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units and any configuration changes made between when the unit was disconnected and reconnected are lost.

## FortiGate HA compatibility with PPPoE and DHCP

FortiGate HA is not compatible with PPP protocols such as PPPoE. FortiGate HA is also not compatible with DHCP. If one or more FortiGate unit interfaces is dynamically configured using DHCP or PPPoE you cannot switch to operate in HA mode. Also, you cannot switch to operate in HA mode if one or more FortiGate unit interfaces is configured as a PPTP or L2TP client.

Configuring an interface for DHCP or PPPoE is only supported in NAT/Route mode. So, usually when configuring HA in Transparent mode an interface being configured for DHCP or PPPoE should not affect HA operation. However, in some cases you may not be able to enable HA if you had configured an interface for DHCP or PPPoE before switching to Transparent mode. So, if you are blocked from operating a Transparent mode FortiGate unit in HA and cannot find another reason for the problem, try switching the FortiGate unit back to NAT/Route mode and setting all interface modes to static before switching to Transparent mode and enabling HA. You could also enable HA before switching to Transparent mode.

You can configure a cluster to act as a DHCP server or a DHCP relay agent. In both active-passive and active-active clusters DHCP relay sessions are always handled by the primary unit. It is possible that a DHCP relay session could be interrupted by a failover. If this occurs the DHCP relay session is not resumed after the failover and the DHCP client may have to repeat the DHCP request.

When a cluster is operating as a DHCP server the primary unit responds to all DHCP requests and maintains the DHCP server address lease database. The cluster also dynamically synchronizes the DHCP server address lease database to the subordinate units. If a failover occurs, the new primary unit will have an up-to-date DHCP server address lease database. Synchronizing the DHCP address lease database prevents the new primary unit from responding incorrectly to new DHCP requests after a failover.

Also, it is possible that when FortiGate units first negotiate to form a cluster that a unit that ends up as a subordinate unit in the cluster will have information in its DHCP address lease database that the cluster unit operating as the primary unit does not have. This can happen if a FortiGate unit responds to DHCP requests while operating as a standalone unit and then when the cluster is formed this unit becomes a subordinate unit. Because of this possibility, after a cluster is formed the DHCP address lease databases of all of the cluster units are merged into one database which is then synchronized to all cluster units.

## HA and distributed clustering

The FGCP supports widely separated cluster units installed in different physical locations. Distributed clusters can have cluster units in different rooms in the same building, different buildings in the same location, or even different geographical sites such as different cities, countries or continents.

Just like any cluster, distributed clusters require heartbeat communication between cluster units. In a distributed cluster this heartbeat communication can take place over the Internet or over other transmission methods including satellite linkups.

Because of the possible distance it may take a relatively long time for heartbeat packets to be transmitted between cluster units. To support a distributed cluster you may need to increase the heartbeat interval so that the cluster expects extra time between heartbeat packets. For information about changing the heartbeat interval and other heartbeat related settings, see [“Modifying heartbeat timing” on page 1298](#).

## Hard disk configuration and HA

If your cluster units include hard disks, all cluster units must have identical hard disk configurations. This means each cluster unit must have same number of hard disks (including AMC and FortiGate Storage Module (FSM) hard disks) and also means that matching hard disks in each cluster unit must be the same size, have the same hard disk format, and have the same number of partitions.

In most cases the default hard disk configuration of the cluster units will be compatible. However, a hard disk formatted by an older FortiGate firmware version may not be compatible with a hard disk formatted by a more recent firmware version. Problems may also arise if you have used the `execute scsi-dev` command to add or change hard disk protections.

If a cluster unit CLI displays hard disk compatibility messages, you may need to use the `execute scsi-dev delete` command to delete partitions. You can also use the `execute formatlogdisk` command to reformat hard disks. In some cases after deleting all partitions and reformatting the hard disks, you may still see hard disk incompatibility messages. If this happens, contact Fortinet Customer Support for assistance.

## FGCP high availability best practices

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Consider adding an Alias to the interfaces used for the HA heartbeat so that you always get a reminder about what these interfaces are being used for.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection. See [“Load balancing UTM sessions, TCP sessions, and UDP sessions” on page 1347](#).
- An advantage of using session pickup is that non-content inspection sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must

be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance). See [“Session failover \(session pick-up\)” on page 1330](#).

- If session pickup is not selected, after a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Users downloading large files may have to restart their download after a failover. Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.
- If you need to enable session pickup, consider enabling session pickup delay to improve performance by reducing the number of sessions that are synchronized. If possible, also consider enabling session synchronization or multiple FortiGate Interfaces. See [“Improving session synchronization performance” on page 1331](#) for more information.
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit. See [“HA MAC addresses and 802.3ad aggregation” on page 1188](#).
- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently. See [“Operating a cluster” on page 1252](#).

## Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

---

- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See [“Enabling or disabling HA heartbeat encryption and authentication” on page 1299](#).
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.

## Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See [“Remote link failover” on page 1325](#).

## Troubleshooting

The following sections in this document contain troubleshooting information:

- [“Troubleshooting HA clusters” on page 1212](#)
- [“Troubleshooting virtual clustering” on page 1238](#)
- [“Troubleshooting full mesh HA” on page 1251](#)
- [“Troubleshooting layer-2 switches” on page 1361](#)

## FGCP HA terminology

The following HA-specific terms are used in this document.

### Cluster

A group of FortiGate units that act as a single virtual FortiGate unit to maintain connectivity even if one of the FortiGate units in the cluster fails.

### Cluster unit

A FortiGate unit operating in a FortiGate HA cluster.

### Device failover

Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device. See also [“Device failover, link failover, and session failover” on page 1130](#).

### Failover

A FortiGate unit taking over processing network traffic in place of another unit in the cluster that suffered a device failure or a link failure.

### Failure

A hardware or software problem that causes a FortiGate unit or a monitored interface to stop processing network traffic.

## FGCP

The FortiGate clustering protocol (FGCP) that specifies how the FortiGate units in a cluster communicate to keep the cluster operating.

## Full mesh HA

Full mesh HA is a method of removing single points of failure on a network that includes an HA cluster. FortiGate models that support redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA includes redundant connections between all network components. If any single component or any single connection fails, traffic switches to the redundant component or connection.

## HA virtual MAC address

When operating in HA mode, all of the interfaces of the primary unit acquire the same HA virtual MAC address. All communications with the cluster must use this MAC address. The HA virtual MAC address is set according to the group ID.

## Heartbeat

Also called FGCP heartbeat or HA heartbeat. The heartbeat constantly communicates HA status and synchronization information to make sure that the cluster is operating properly.

## Heartbeat device

An ethernet network interface in a cluster that is used by the FGCP for heartbeat communications among cluster units.

## Heartbeat failover

If an interface functioning as the heartbeat device fails, the heartbeat is transferred to another interface also configured as an HA heartbeat device.

## Hello state

In the hello state a cluster unit has powered on in HA mode, is using HA heartbeat interfaces to send hello packets, and is listening on its heartbeat interfaces for hello packets from other FortiGate units. Hello state may appear in HA log messages.

## High availability

The ability that a cluster has to maintain a connection when there is a device or link failure by having another unit in the cluster take over the connection, without any loss of connectivity. To achieve high availability, all FortiGate units in the cluster share session and configuration information.

## Interface monitoring

You can configure interface monitoring (also called port monitoring) to monitor FortiGate interfaces to verify that the monitored interfaces are functioning properly and connected to their networks. If a monitored interface fails or is disconnected from its network the interface leaves the cluster and a link failover occurs. For more information about interface monitoring, see [“Link failover \(port monitoring or interface monitoring\)” on page 1319](#).

## Link failover

Link failover means that if a monitored interface fails, the cluster reorganizes to re-establish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic. See also [“Device failover, link failover, and session failover” on page 1130](#).

## Load balancing

Also known as active-active HA. All units in the cluster process network traffic. The FGCP employs a technique similar to unicast load balancing. The primary unit interfaces are assigned virtual MAC addresses which are associated on the network with the cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit can process packets itself, or propagate them to subordinate units according to a load balancing schedule. Communication between the cluster units uses the actual cluster unit MAC addresses.

## Monitored interface

An interface that is monitored by a cluster to make sure that it is connected and operating correctly. The cluster monitors the connectivity of this interface for all cluster units. If a monitored interface fails or becomes disconnected from its network, the cluster will compensate.

## Primary unit

Also called the primary cluster unit, this cluster unit controls how the cluster operates. The primary unit sends hello packets to all cluster units to synchronize session information, synchronize the cluster configuration, and to synchronize the cluster routing table. The hello packets also confirm for the subordinate units that the primary unit is still functioning.

The primary unit also tracks the status of all subordinate units. When you start a management connection to a cluster, you connect to the primary unit.

In an active-passive cluster, the primary unit processes all network traffic. If a subordinate unit fails, the primary unit updates the cluster configuration database.

In an active-active cluster, the primary unit receives all network traffic and re-directs this traffic to subordinate units. If a subordinate unit fails, the primary unit updates the cluster status and redistributes load balanced traffic to other subordinate units in the cluster.

The FortiGate firmware uses the term master to refer to the primary unit.

## Session failover

Session failover means that a cluster maintains active network sessions after a device or link failover. FortiGate HA does not support session failover by default. To enable session failover you must change the HA configuration to select Enable Session Pick-up. See also [“Device failover, link failover, and session failover” on page 1130](#).

## Session pickup

If you enable session pickup for a cluster, if the primary unit fails or a subordinate unit in an active-active cluster fails, all communication sessions with the cluster are maintained or picked up by the cluster after the cluster negotiates to select a new primary unit.

If session pickup is not a requirement of your HA installation, you can disable this option to save processing resources and reduce the network bandwidth used by HA session synchronization. In many cases interrupted sessions will resume on their own after a failover even if session pickup is not enabled. You can also enable session pickup delay to reduce the number of sessions that are synchronized by session pickup.

## Standby state

A subordinate unit in an active-passive HA cluster operates in the standby state. In a virtual cluster, a subordinate virtual domain also operates in the standby state. The standby state is actually a hot-standby state because the subordinate unit or subordinate virtual domain is not processing traffic but is monitoring the primary unit session table to take the place of the primary unit or primary virtual domain if a failure occurs.

In an active-active cluster all cluster units operate in a work state.

When standby state appears in HA log messages this usually means that a cluster unit has become a subordinate unit in an active-passive cluster or that a virtual domain has become a subordinate virtual domain.

## State synchronization

The part of the FGCP that maintains connections after failover.

## Subordinate unit

Also called the subordinate cluster unit, each cluster contains one or more cluster units that are not functioning as the primary unit. Subordinate units are always waiting to become the primary unit. If a subordinate unit does not receive hello packets from the primary unit, it attempts to become the primary unit.

In an active-active cluster, subordinate units keep track of cluster connections, keep their configurations and routing tables synchronized with the primary unit, and process network traffic assigned to them by the primary unit. In an active-passive cluster, subordinate units do not process network traffic. However, active-passive subordinate units do keep track of cluster connections and do keep their configurations and routing tables synchronized with the primary unit.

The FortiGate firmware uses the terms slave and subsidiary unit to refer to a subordinate unit.

## Virtual clustering

Virtual clustering is an extension of the FGCP for FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

## Work state

The primary unit in an active-passive HA cluster, a primary virtual domain in a virtual cluster, and all cluster units in an active-active cluster operate in the work state. A cluster unit operating in the work state processes traffic, monitors the status of the other cluster units, and tracks the session table of the cluster.

When work state appears in HA log messages this usually means that a cluster unit has become the primary unit or that a virtual domain has become a primary virtual domain.

## HA web-based manager options

Go to *System > Config > HA* to change HA options. You can set the following options to put a FortiGate unit into HA mode. You can also change any of these options while the cluster is operating.

You can configure HA options for a FortiGate unit with virtual domains (VDOMs) enabled by logging into the web-based manager as the global admin administrator and going to *System > Config > HA*.

If already operating in HA mode, go to *System > Config > HA* to display the cluster members list (see [“Cluster members list” on page 1268](#)).

Go to *System > Config > HA* and select *View HA Statistics* to view statistics about cluster operation. See [“Viewing HA statistics” on page 1271](#).

If your cluster uses virtual domains, you are configuring HA virtual clustering. Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below and see [“Virtual clusters” on page 1217](#).

HA is not compatible with PPP protocols such as PPPoE. HA is also not compatible with DHCP. If one or more FortiGate interfaces is dynamically configured using DHCP or PPPoE, you cannot switch to operate in HA mode. You also cannot switch to operate in HA mode if one or more FortiGate interfaces is configured as a PPTP or L2TP client or if the FortiGate unit is configured for standalone session synchronization.

<b>Mode</b>	<p>Select an HA mode for the cluster or return the FortiGate unit in the cluster to standalone mode. When configuring a cluster, you must set all members of the HA cluster to the same HA mode. You can select <i>Standalone</i> (to disable HA), <i>Active-Passive</i>, or <i>Active-Active</i>.</p> <p>If virtual domains are enabled you can select <i>Active-Passive</i> or <i>Standalone</i>.</p>
<b>Device Priority</b>	<p>Optionally set the device priority of the cluster FortiGate unit. Each FortiGate unit in a cluster can have a different device priority. During HA negotiation, the FortiGate unit with the highest device priority usually becomes the primary unit. See <a href="#">“Primary unit selection” on page 1131</a>.</p> <p>In a virtual cluster configuration, each cluster FortiGate unit can have two different device priorities, one for each virtual cluster. During HA negotiation, the FortiGate unit with the highest device priority in a virtual cluster becomes the primary FortiGate unit for that virtual cluster.</p> <p>Changes to the device priority are not synchronized. You can accept the default device priority when first configuring a cluster.</p>
<b>Reserve Management Port for Cluster Member</b>	<p>You can provide direct management access to individual cluster units by reserving a management interface as part of the HA configuration. Once this management interface is reserved, you can configure a different IP address, administrative access and other interface settings for this interface for each cluster unit. Then by connecting this interface of each cluster unit to your network you can manage each cluster unit separately from a different IP address. See <a href="#">“Managing individual cluster units using a reserved management interface” on page 1254</a>.</p>

<b>Group Name</b>	<p>Enter a name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units.</p>
<b>Password</b>	<p>Enter a password to identify the cluster. The password must be the same for all cluster FortiGate units before the cluster FortiGate units can form a cluster.</p> <p>Two clusters on the same network must have different passwords.</p> <p>The password is synchronized to all cluster units in an operating cluster. If you change the password of one cluster unit the change is synchronized to all cluster units.</p>
<b>Enable Session pickup</b>	<p>Select to enable session pickup so that if the primary unit fails, sessions are picked up by the cluster unit that becomes the new primary unit.</p> <p>You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce HA CPU usage and reduce HA heartbeat network bandwidth usage. See <a href="#">“Session failover (session pick-up)” on page 1330</a>.</p>
<b>Port Monitor</b>	<p>Select to enable or disable monitoring FortiGate interfaces to verify the monitored interfaces are functioning properly and are connected to their networks. See <a href="#">“Link failover (port monitoring or interface monitoring)” on page 1319</a>.</p> <p>If a monitored interface fails or is disconnected from its network, the interface leaves the cluster and a link failover occurs. The link failover causes the cluster to reroute the traffic being processed by that interface to the same interface of another cluster FortiGate unit that still has a connection to the network. This other cluster FortiGate unit becomes the new primary unit.</p> <p>Port monitoring (also called interface monitoring) is disabled by default. Leave port monitoring disabled until the cluster is operating and then only enable port monitoring for connected interfaces.</p> <p>You can monitor up to 64 interfaces.</p>

---

**Heartbeat Interface**

Select to enable or disable HA heartbeat communication for each interface in the cluster and set the heartbeat interface priority. The heartbeat interface with the highest priority processes all heartbeat traffic. If two or more heartbeat interfaces have the same priority, the heartbeat interface with the lowest hash map order value processes all heartbeat traffic. The web-based manager lists interfaces in alphanumeric order:

- port1
- port2 through 9
- port10

Hash map order sorts interfaces in the following order:

- port1
- port10
- port2 through port9

The default heartbeat interface configuration is different for each FortiGate model. This default configuration usually sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration or change it as required.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0.

You must select at least one heartbeat interface. If heartbeat communication is interrupted, the cluster stops processing traffic. See [“HA heartbeat and communication between cluster units” on page 1293](#).

You can select up to 8 heartbeat interfaces. This limit only applies to units with more than 8 physical interfaces.

---

**VDOM partitioning**

If you are configuring virtual clustering, you can set the virtual domains to be in virtual cluster 1 and the virtual domains to be in virtual cluster 2. The root virtual domain must always be in virtual cluster 1. See [“Virtual clusters” on page 1217](#).

---

# Configuring and connecting HA clusters

This chapter contains general procedures and descriptions as well as detailed configuration examples that describe how to configure FortiGate HA clusters.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

This chapter contains the following sections:

- [About the procedures in this chapter](#)
- [Example: NAT/Route mode active-passive HA configuration](#)
- [Example: Transparent mode active-active HA configuration](#)
- [Example: advanced Transparent mode active-active HA configuration](#)
- [Example: converting a standalone FortiGate unit to a cluster](#)
- [Example: adding a new unit to an operating cluster](#)
- [Example: replacing a failed cluster unit](#)
- [Example: HA and 802.3ad aggregated interfaces](#)
- [Example: HA and redundant interfaces](#)
- [Troubleshooting HA clusters](#)

## About the procedures in this chapter

The procedures in this chapter describe some of many possible sequences of steps for configuring HA clustering. As you become more experienced with FortiOS HA you may choose to use a different sequence of configuration steps.

For simplicity, many of these procedures assume that you are starting with new FortiGate units set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

## Example: NAT/Route mode active-passive HA configuration

This section describes a simple HA network topology that includes an HA cluster of two FortiGate-620B units in NAT/Route mode installed between an internal network and the Internet.

- [Example NAT/Route mode HA network topology](#)
- [General configuration steps](#)
- [Configuring a NAT/Route mode active-passive cluster of two FortiGate-620B units - web-based manager](#)
- [Configuring a NAT/Route mode active-passive cluster of two FortiGate-620B units - CLI](#)

## Example NAT/Route mode HA network topology

Figure 190 shows a typical FortiGate-620B HA cluster consisting of two FortiGate-620B units (620\_ha\_1 and 620\_ha\_2) connected to the same internal (port2) and external (port1) networks.

**Figure 190:**Example NAT/Route mode HA network topology

Port3 and port4 are the default FortiGate-620B heartbeat interfaces. Because the cluster consists of two FortiGate units, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular ethernet cables.

## General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

### General configuration steps

1. Configure the FortiGate units for HA operation.
  - Optionally change each unit's host name.
  - Configure HA.
2. Connect the cluster to the network.
3. Confirm that the cluster units are operating as a cluster and add basic configuration settings to the cluster.
  - View cluster status from the web-based manager or CLI.
  - Add a password for the admin administrative account.
  - Change the IP addresses and netmasks of the internal and external interfaces.
  - Add a default route.

## Configuring a NAT/Route mode active-passive cluster of two FortiGate-620B units - web-based manager

Use the following procedures to configure two FortiGate-620B units for NAT/Route HA operation using the FortiGate web-based manager. These procedures assume you are starting with two FortiGate-620B units with factory default settings.

Give each cluster unit a unique host name to make the individual units easier to identify when they are part of a functioning cluster. The default FortiGate unit host name is the FortiGate serial number. You may want to change this host name to something more meaningful for your network.

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP you will not be able to configure HA.

### To configure the first FortiGate-620B unit (host name 620\_ha\_1)

1. Power on the first FortiGate unit.
2. On your management computer with an Ethernet connection, set the static IP address to 192.168.1.2 and the netmask to 255.255.255.0.
3. On a management computer, start a web browser and browse to the address <https://192.168.1.99> (remember to include the “s” in https://).  
The FortiGate login is displayed.
4. Type *admin* in the *Name* field and select *Login*.  
The FortiGate dashboard is displayed.
5. On the *System Information* dashboard widget beside *Host Name*, select *Change*.
6. Enter a new Host Name for this FortiGate unit.

<b>New Name</b>	620_ha_1
-----------------	----------

7. Select OK.
8. Go to *System > Config > HA* and change the following settings:

<b>Mode</b>	Active-Passive
-------------	----------------

<b>Group Name</b>	example1.com
-------------------	--------------

<b>Password</b>	HA_pass_1
-----------------	-----------

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each unit in the cluster.

9. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC](#)

[addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address (Permanent\_HWaddr):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

**10.** Power off the first FortiGate unit (620\_ha\_1).

### **To configure the second FortiGate-620B unit (host name 620\_ha\_2)**

1. Power on the second FortiGate unit.
2. On a management computer, start a web browser and browse to the address `https://192.168.1.99` (remember to include the “s” in `https://`).

The FortiGate login is displayed.

3. Type *admin* in the *Name* field and select *Login*.  
The FortiGate dashboard is displayed.
4. On the *System Information* dashboard widget, beside *Host Name* select *Change*.
5. Enter a new Host Name for this FortiGate unit.

---

<b>New Name</b>	620_ha_2
-----------------	----------

---

6. Select OK.
7. Go to *System > Config > HA* and change the following settings:

---

<b>Mode</b>	Active-Passive
-------------	----------------

---

<b>Group Name</b>	example1.com
-------------------	--------------

---

<b>Password</b>	HA_pass_1
-----------------	-----------

---

8. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

9. Power off the second FortiGate unit.

### To connect the cluster to the network

1. Connect the port1 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of 620\_ha\_1 and 620\_ha\_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

### To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate unit. You could have performed the following configuration steps separately on each FortiGate unit before you connected them to form a cluster.

---

1. Start Internet Explorer and browse to the address <https://192.168.1.99> (remember to include the “s” in https://).

The FortiGate Login is displayed.

2. Type `admin` in the *Name* field and select Login.

The FortiGate dashboard is displayed.

The System Information dashboard widget shows the *Cluster Name* (example1.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

**Figure 191:**Sample FortiGate-620B System Information dashboard widget

System Information		
Cluster Name	example1.com	
Cluster Members	620_ha_2/FG600B3908600825	(Master)
	620_ha_1/FG600B3908600705	(Slave)
Serial Number	FG600B3908600825	
Operation Mode	NAT [Change]	
HA Status	Active-Passive [Configure]	
System Time	Wed Feb 9 14:35:11 2011 [Change]	
Firmware Version	v4.0,build0415,110126 (Interim) [Update]	
System Configuration	Last Backup: N/A [Backup] [Restore]	
Current Administrator	admin [Change Password] /4 in Total [Details]	
Uptime	13 day(s) 7 hour(s) 34 min(s)	
Virtual Domain	Disabled [Enable]	

3. Go to *System > Config > HA* to view the cluster members list.

The list shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

**Figure 192:**Sample FortiGate-620B cluster members list

HA Cluster		View HA Statistics		
	Cluster Member	Hostname	Role	Priority
  FortiGate 620B	 FortiGate 620B	620_ha_2	MASTER	128
	 FortiGate 620B	620_ha_1	SLAVE	128

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add basic configuration settings to the cluster

Use the following steps to configure the cluster to connect to its network. The following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster web-based manager.
2. Go to *System > Admin > Administrators*.
3. For *admin*, select the *Change Password* icon
4. Enter and confirm a new password.

5. Select OK.
6. Go to *System > Network > Interfaces*.
7. Edit the *port2* interface and change *IP/Netmask* to 10.11.101.100/24.
8. Select OK.

After changing the IP address of the port1 interface you may have to change the IP address of your management computer and then reconnect to the port1 interface using the 172.20.120.141 IP address.

9. Edit the *port1* interface and change *IP/Netmask* to 172.20.120.141/24.
10. Select OK.
11. Go to *Router > Static > Static Routes*.
12. Change the default route.

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Gateway</b>	172.20.120.2
<b>Device</b>	port1
<b>Distance</b>	10

13. Select OK.

## Configuring a NAT/Route mode active-passive cluster of two FortiGate-620B units - CLI

Use the following procedures to configure two FortiGate-620B units for NAT/Route HA operation using the FortiGate CLI. These procedures assume you are starting with two FortiGate-620B units with factory default settings.

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP you will not be able to configure HA.

### To configure the first FortiGate-620B unit (host name 620\_ha\_1)

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal (or any terminal emulation program), enter a name for the connection, and select OK.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select OK.
5. Select the following port settings and select OK.

<b>Bits per second</b>	9600
<b>Data bits</b>	8

<b>Parity</b>	None
<b>Stop bits</b>	1
<b>Flow control</b>	None

6. Press Enter to connect to the FortiGate CLI.

The FortiGate unit CLI login prompt appears.

If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7. Type `admin` and press Enter twice.
8. Change the host name for this FortiGate unit.

```
config system global
    set hostname 620_ha_1
end
```

9. Configure HA settings.

```
config system ha
    set mode a-p
    set group-name example1.com
    set password HA_pass_1
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12

- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address

(Permanent\_HWaddr):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

#### 10. Display the HA configuration (optional).

```
get system ha
  group-id           : 0
  group-name         : example1.com
  mode               : a-p
  password           : *
  hbdev              : "port3" 50 "port4" 50
  session-sync-dev   :
  route-ttl          : 10
  route-wait         : 0
  route-hold         : 10
  sync-config        : enable
  encryption         : disable
  authentication     : disable
  hb-interval        : 2
  hb-lost-threshold  : 6
  helo-holddown      : 20
  arps               : 5
  arps-interval      : 8
  session-pickup     : disable
  link-failed-signal : disable
  uninterruptible-upgrade: enable
  ha-mgmt-status     : disable
  ha-eth-type        : 8890
  hc-eth-type        : 8891
  l2ep-eth-type      : 8893
  subsecond          : disable
  vcluster2          : disable
  vcluster-id        : 1
  override           : disable
```

```

priority          : 128
monitor           :

pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom              : "root"

```

## 11. Power off the FortiGate unit.

### To configure the second FortiGate-620B unit (host name 620\_ha\_2)

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select OK.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select OK.
5. Select the following port settings and select OK.

<b>Bits per second</b>	9600
<b>Data bits</b>	8
<b>Parity</b>	None
<b>Stop bits</b>	1
<b>Flow control</b>	None

6. Press Enter to connect to the FortiGate CLI.  
The FortiGate unit CLI login prompt appears.
7. Type `admin` and press Enter twice.
8. Change the host name for this FortiGate unit.

```

config system global
    set hostname 620_ha_2
end

```

9. Configure HA settings.

```

config system ha
    set mode a-p
    set group-name example1.com
    set password HA_pass_1
end

```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

## 10. Display the HA configuration (optional).

```
get system ha
  group-id           : 0
  group-name         : example1.com
  mode               : a-p
  password           : *
  hbdev              : "port3" 50 "port4" 50
  session-sync-dev   :
  route-ttl          : 10
  route-wait         : 0
  route-hold         : 10
  sync-config        : enable
  encryption         : disable
  authentication     : disable
  hb-interval        : 2
  hb-lost-threshold  : 6
  helo-holddown      : 20
  arps               : 5
  arps-interval      : 8
  session-pickup     : disable
  link-failed-signal : disable
  uninterruptible-upgrade: enable
  ha-mgmt-status     : disable
  ha-eth-type        : 8890
  hc-eth-type        : 8891
  l2ep-eth-type      : 8893
  subsecond          : disable
  vcluster2          : disable
  vcluster-id        : 1
  override           : disable
  priority           : 128
  monitor            :
  pingserver-monitor-interface:
  pingserver-failover-threshold: 0
  pingserver-flip-timeout: 60
  vdom               : "root"
```

## 11. Power off the FortiGate unit.

### To connect the cluster to the network

1. Connect the port1 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of 620\_ha\_1 and 620\_ha\_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

## 5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

### To view cluster status

Use the following steps to view cluster status from the CLI.

#### 1. Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.
- If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.
- If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

---

#### 2. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
Model: 620
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
Master:128 620_ha_2          FG600B3908600825 0
Slave :128 620_ha_1          FG600B3908600705 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add basic configuration settings to the cluster

Use the following steps to add some basic settings to the cluster so that it can connect to the network.

1. Log into the primary unit CLI.
2. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <password_str>
  end
```

3. Configure the port1 and port2 interfaces.

```
config system interface
  edit port1
    set ip 172.20.120.141/24
  next
  edit port2
    set ip 10.11.101.100/24
  end
```

4. Add a default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device port1
  end
```

## Example: Transparent mode active-active HA configuration

This section describes a simple HA network topology that includes an HA cluster of two FortiGate-620B units installed between an internal network and the Internet and running in Transparent mode.

- [Example Transparent mode HA network topology](#)
- [General configuration steps](#)

### Example Transparent mode HA network topology

[Figure 193](#) shows a Transparent mode FortiGate-620B HA cluster consisting of two FortiGate-620B units (620\_ha\_1 and 620\_ha\_2) installed between the Internet and internal network. The topology includes a router that performs NAT between the internal network and the Internet. The cluster management IP address is 10.11.101.100.

**Figure 193:**Transparent mode HA network topology

Port3 and port4 are the default FortiGate-620B heartbeat interfaces. Because the cluster consists of two FortiGate units, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular ethernet cables.

## General configuration steps

This section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

In this example, the configuration steps are identical to the NAT/Route mode configuration steps until the cluster is operating. When the cluster is operating, you can switch to Transparent mode and add basic configuration settings to cluster.

### General configuration steps

1. Configure the FortiGate units for HA operation.
  - Optionally change each unit's host name.
  - Configure HA.
2. Connect the cluster to the network.
3. Confirm that the cluster units are operating as a cluster.
4. Switch the cluster to Transparent mode and add basic configuration settings to the cluster.
  - Switch to Transparent mode, add the management IP address and a default route.
  - Add a password for the admin administrative account.
  - View cluster status from the web-based manager or CLI.

## Configuring a Transparent mode active-active cluster of two FortiGate-620B units - web-based manager

Use the following procedures to configure the FortiGate-620B units for HA operation using the FortiGate web-based manager. These procedures assume you are starting with two FortiGate-620B units with factory default settings.

Waiting until you have established the cluster to switch to Transparent mode means fewer configuration steps because you can switch the mode of the cluster in one step.

### To configure the first FortiGate-620B unit (host name 620\_ha\_1)

1. Power on the first FortiGate unit.
2. Set the IP address of a management computer with an Ethernet connection to the static IP address 192.168.1.2 and a netmask of 255.255.255.0.
3. On a management computer, start a web browser and browse to the address <https://192.168.1.99> (remember to include the “s” in https://).  
The FortiGate login is displayed.
4. Type *admin* in the *Name* field and select *Login*.  
The FortiGate dashboard is displayed.
5. On the *System Information* dashboard widget, beside *Host Name* select *Change*.
6. Enter a new Host Name for this FortiGate unit.

<b>New Name</b>	620_ha_1
-----------------	----------

7. Select OK.
8. Go to *System > Config > HA* and change the following settings:

<b>Mode</b>	Active-Active
-------------	---------------

<b>Group Name</b>	example2.com
-------------------	--------------

<b>Password</b>	HA_pass_2
-----------------	-----------

This is the minimum recommended configuration for an active-active HA cluster. You can configure other HA options at this point, but if you wait until the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

9. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02

- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (MAC) and the port1 permanent MAC address

(Permanent\_HWaddr):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

#### 10. Power off the first FortiGate unit.

#### To configure the second FortiGate-620B unit (host name 620\_ha\_2)

1. Power on second FortiGate unit.
2. On a management computer, start Internet Explorer and browse to the address <https://192.168.1.99> (remember to include the “s” in https://).  
The FortiGate login is displayed.
3. Type *admin* in the *Name* field and select *Login*.  
The FortiGate dashboard is displayed.
4. On the *System Information* dashboard widget, beside *Host Name* select *Change*.

5. Enter a new Host Name for this FortiGate unit.

---

<b>New Name</b>	620_ha_2
-----------------	----------

---

6. Select OK.
7. Go to *System > Config > HA* and change the following settings:

---

<b>Mode</b>	Active-Active
<b>Group Name</b>	example2.com
<b>Password</b>	HA_pass_2

---

8. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

9. Power off the second FortiGate unit.

#### To connect the cluster to the network

1. Connect the port1 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of 620\_ha\_1 and 620\_ha\_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

#### To switch the cluster to Transparent mode

Switching from NAT/Route to Transparent mode involves adding the Transparent mode management IP address and default route.

Since configuration changes are synchronized to all cluster units, switching the cluster to operate in Transparent mode once the cluster is operating is the same as switching an individual FortiGate unit to Transparent mode. You could have performed the following configuration steps separately on each FortiGate unit before you connected them to form a cluster.

1. Start a web browser and browse to the address `https://192.168.1.99` (remember to include the “s” in `https://`).
- The FortiGate Login is displayed.
2. Type admin in the Name field and select Login.

3. Under System Information, beside *Operation Mode* select *Change*.
4. Set Operation Mode to Transparent.
5. Configure basic Transparent mode settings.

<b>Operation Mode</b>	Transparent
<b>Management IP/Mask</b>	10.11.101.100/24
<b>Default Gateway</b>	10.11.101.2

6. Select Apply.

The cluster switches to operating in Transparent mode. The virtual MAC addresses assigned to the cluster interfaces do not change.

### To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate unit. You could have performed the following configuration steps separately on each FortiGate unit before you connected them to form a cluster.

1. Start Internet Explorer and browse to the address <https://10.11.101.100> (remember to include the “s” in https://).

The FortiGate Login is displayed.

2. Type admin in the Name field and select Login.

The FortiGate dashboard is displayed.

The System Information dashboard widget shows the *Cluster Name* (example2.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

3. Go to *System > Config > HA* to view the cluster members list.

The list shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add basic configuration settings to the cluster

Use the following steps to configure the cluster. Note that the following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster web-based manager.
2. Go to *System > Admin > Administrators*.
3. For *admin*, select the *Change Password* icon
4. Enter and confirm a new password.

5. Select OK.

You added a default gateway when you switched to Transparent mode so you don't need to add a default route as part of the basic configuration of the cluster at this point.

## Configuring a Transparent mode active-active cluster of two FortiGate-620B units - CLI

Use the following procedures to configure the FortiGate-620B units for Transparent mode HA operation using the FortiGate CLI.

### To configure each FortiGate unit for HA operation

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select OK.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select OK.
5. Select the following port settings and select OK.

<b>Bits per second</b>	9600
------------------------	------

<b>Data bits</b>	8
------------------	---

<b>Parity</b>	None
---------------	------

<b>Stop bits</b>	1
------------------	---

<b>Flow control</b>	None
---------------------	------

6. Press Enter to connect to the FortiGate CLI.

The FortiGate unit CLI login prompt appears. If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7. Type `admin` and press Enter twice.
8. Change the host name for this FortiGate unit. For example:

```
config system global
    set hostname 620_ha_1
end
```

## 9. Configure HA settings.

```
config system ha
    set mode a-a
    set group-name example2.com
    set password HA_pass_2
end
```

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1

```

interface virtual MAC address (MAC) and the port1 permanent MAC address
(Permanent_HWaddr):
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.

```

#### 10. Display the HA configuration (optional).

```

get system ha
  group-id           : 0
  group-name         : example2.com
  mode               : a-a
  password           : *

  vdom               : "root"

```

#### 11. Power off the FortiGate unit.

### To configure the second FortiGate-620B unit (host name 620\_ha\_2)

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select OK.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select OK.
5. Select the following port settings and select OK.

<b>Bits per second</b>	9600
<b>Data bits</b>	8
<b>Parity</b>	None
<b>Stop bits</b>	1
<b>Flow control</b>	None

6. Press Enter to connect to the FortiGate CLI.

The FortiGate unit CLI login prompt appears. If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7. Type `admin` and press Enter twice.
8. Change the host name for this FortiGate unit.

```
config system global
    set hostname 620_ha_2
end
```

9. Configure HA settings.

```
config system ha
    set mode a-a
    set group-name example2.com
    set password HA_pass_2
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

## 10. Display the HA configuration (optional).

```
get system ha
  group-id           : 0
  group-name         : example2.com
  mode               : a-a
  password           : *
  hbdev              : "port3" 50 "port4" 50
  session-sync-dev   :
  route-ttl          : 10
  route-wait         : 0
  route-hold         : 10
  sync-config        : enable
  encryption         : disable
  authentication     : disable
  hb-interval        : 2
  hb-lost-threshold  : 6
  helo-holddown      : 20
  arps               : 5
  arps-interval      : 8
  session-pickup     : disable
  link-failed-signal : disable
  uninterruptible-upgrade: enable
  ha-mgmt-status     : disable
  ha-eth-type        : 8890
  hc-eth-type        : 8891
  l2ep-eth-type      : 8893
  subsecond          : disable
  vcluster2          : disable
  vcluster-id        : 1
  override           : disable
  priority           : 128
  monitor            :
  pingserver-monitor-interface:
  pingserver-failover-threshold: 0
  pingserver-flip-timeout: 60
  vdom               : "root"
```

## 11. Power off the FortiGate unit.

### To connect the cluster to the network

1. Connect the port1 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of 620\_ha\_1 and 620\_ha\_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

**To connect to the cluster CLI and switch the cluster to Transparent mode**

1. Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.
- If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.
- If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode. See [“Troubleshooting the initial cluster configuration” on page 1213](#).

---

2. Change to transparent mode.

```
config system settings
    set opmode transparent
    set manageip 192.168.20.3/24
    set gateway 192.168.20.1
end
```

The cluster switches to Transparent Mode, and your administration session is disconnected.

You can now connect to the cluster CLI using SSH to connect to the cluster internal interface using the management IP address (192.168.20.3).

**To view cluster status**

Use the following steps to view cluster status from the CLI.

1. Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.
- If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.

- If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

2. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
Model: 620
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 620_ha_2          FG600B3908600825 0
Slave :128 620_ha_1          FG600B3908600705 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add a password for the admin administrative account

1. Add a password for the admin administrative account.

```
config system admin
edit admin
set password <psswr>
end
```

## Example: advanced Transparent mode active-active HA configuration

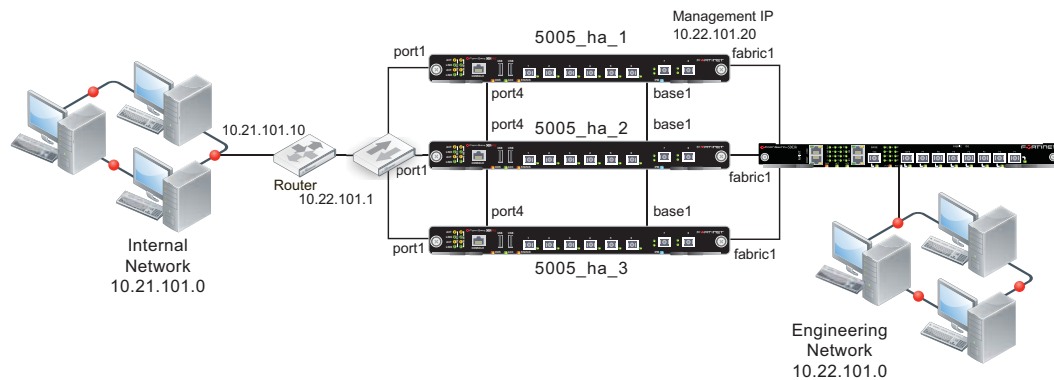

This section describes a more complex HA network topology that includes an HA cluster of three FortiGate-5002FA2 units running in Transparent mode and installed between an internal network and an engineering network.

- [Example Transparent mode HA network topology](#)
- [General configuration steps](#)

## Example Transparent mode HA network topology

Figure 194 shows a Transparent mode FortiGate-5005FA2 HA cluster consisting of three FortiGate-5005FA2 units (5005\_ha\_1, 5005\_ha\_2, and 5005\_ha\_3) installed in a FortiGate-5000 series chassis with one FortiSwitch-5003A board. The cluster applies virus scanning to traffic passing between an engineering network and an internal network. The topology includes a router that performs NAT between the internal network and the engineering network. The cluster is connected to the engineering network with an management IP address of 10.22.101.20. This IP address is on the engineering network subnet.

**Figure 194:**Transparent mode HA network topology

By default fabric1 and fabric2 are the FortiGate-5005FA2 heartbeat interfaces. This example changes the heartbeat configuration to use the base1 and port4 interfaces for the heartbeat. The base1 connection is handled using the base backplane channel switched by the FortiSwitch-5003A board. The port4 connection is handled by connecting the port4 interfaces together using a switch.

The cluster connects to the engineering network using fabric1. The FortiSwitch-5003A board provides switching for the fabric1 interfaces and the fabric1 connection to the engineering network.

## Configuring a Transparent mode active-active cluster of three FortiGate-5005FA2 units - web-based manager

These procedures assume you are starting with three FortiGate-5005FA2 units with factory default settings but not installed in chassis slots and a FortiSwitch-5003A board installed in chassis slot 1. The chassis is powered on. This configuration works for a FortiGate-5050 chassis or for a FortiGate-5140 chassis. No configuration changes to the FortiSwitch-5003A board are required.

### To configure the FortiGate-5005FA2 units

1. Power on the first FortiGate unit by inserting it into chassis slot 5.
2. Connect port1 to the network and log into the web-based manager.
3. On the *System Information* dashboard widget, beside *Host Name* select *Change*.
4. Enter a new Host Name for this FortiGate unit.

<b>New Name</b>	5005_ha_1
-----------------	-----------

5. Select OK.
6. Go to *System > Network > Interfaces* and select *Show backplane interfaces*.

7. Make sure the administrative status and link status is for base1 and fabric1.

You can edit the interface to set the administrative status to up. The link status will be up if the administrative status is up and the FortiGate-5005FA2 board can connect to the FortiSwitch-5003A board.

8. Go to *System > Config > HA* and change the following settings:

Mode	Active-Active	
Group Name	example3.com	
Password	HA_pass_3	
Heartbeat Interface		
	Enable	Priority
base1	Select	50
fabric1	Clear check box	0
fabric2	Clear check box	0
port4	Select	50

9. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-5005FA2 interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: 00-09-0f-09-00-00
- base2 interface virtual MAC: 00-09-0f-09-00-01
- fabric1 interface virtual MAC: 00-09-0f-09-00-02
- fabric2 interface virtual MAC: 00-09-0f-09-00-03
- port1 interface virtual MAC: 00-09-0f-09-00-04
- port2 interface virtual MAC: 00-09-0f-09-00-05
- port3 interface virtual MAC: 00-09-0f-09-00-06
- port4 interface virtual MAC: 00-09-0f-09-00-07
- port5 interface virtual MAC: 00-09-0f-09-00-08
- port6 interface virtual MAC: 00-09-0f-09-00-09
- port7 interface virtual MAC: 00-09-0f-09-00-0a
- port8 interface virtual MAC: 00-09-0f-09-00-0b

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use

the following command to view the port1 interface virtual MAC address (Current\_HWaddr) and the port1 permanent MAC address (Permanent\_HWaddr):

```
get hardware nic port1
.
.
.
Current_HWaddr      00:09:0f:09:00:04
Permanent_HWaddr    00:09:0f:71:0a:dc
.
.
.
```

**10.**Power off the first FortiGate unit.

**11.**Repeat these steps for the second and third FortiGate units, with the following difference.

Set the second FortiGate unit host name to:

<b>New Name</b>	5005_ha_2
-----------------	-----------

Set the third FortiGate unit host name to:

<b>New Name</b>	5005_ha_3
-----------------	-----------

As you insert and configure each FortiGate unit, they will negotiate and join the cluster using the base1 interface for HA heartbeat communication.

### To connect the cluster to the network

1. Connect the port1 interfaces of the cluster to a switch that can connect to the router and the internal network.
2. Connect the port4 interfaces of the cluster units together using a switch.  
These interfaces become the backup heartbeat interface.
3. Connect one of the FortiSwitch-5003A front panel fabric interfaces (for example, F3) to the engineering network.

### To switch the cluster to operate in Transparent mode

Switching from NAT/Route to Transparent mode also involves adding the Transparent mode management IP address and default route.

1. Log into the web-based manager.
2. Under System Information, beside *Operation Mode* select *Change*.
3. Set *Operation Mode* to *Transparent*.
4. Configure basic Transparent mode settings.

<b>Operation Mode</b>	Transparent
<b>Management IP/Mask</b>	10.22.101.20/24
<b>Default Gateway</b>	10.22.101.1

5. Select Apply.

The cluster switches to operating in Transparent mode. The virtual MAC addresses assigned to the cluster interfaces do not change. You must login again using the new TP address.

### To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

The System Information dashboard widget shows the *Cluster Name* (example3.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

2. Go to *System > Config > HA* to view the cluster members list.

The list shows three cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add basic configuration settings to the cluster

Use the following steps to configure the cluster. The following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster web-based manager.
2. Go to *System > Admin > Administrators*.
3. For *admin*, select the *Change Password* icon
4. Enter and confirm a new password.
5. Select OK.

The default route was changed when you switched to Transparent mode.

## Configuring a Transparent mode active-active cluster of three FortiGate-5005FA2 units - CLI

Use the following procedures to configure the three FortiGate-5005FA2 units for Transparent mode HA operation using the FortiGate CLI.

### To configure the FortiGate-5005FA2 units

1. Power on the first FortiGate unit by inserting it into chassis slot 5.
2. Connect port1 to the network and log into the CLI.

You can also use a console connection.

3. Change the host name for this FortiGate unit. For example:

```
config system global
    set hostname 5005_ha_1
end
```

4. Enable showing backplane interfaces.

```
config system global
    set show-backplane-intf enable
end
```

5. Make sure the administrative status and link status is up for base1 and fabric1.

Enter `get system interface` to view the status of these interfaces.

You can use the following commands to set the administrative status to up for these interfaces.

```
config system interface
    edit base1
        set status up
    next
    edit fabric1
        set status up
end
```

6. Configure HA settings.

```
config system ha
    set mode a-a
    set group-name example3.com
    set password HA_pass_3
    set hbdev base1 50 port4 50
end
```

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

---

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: 00-09-0f-09-00-00
- base2 interface virtual MAC: 00-09-0f-09-00-01
- fabric1 interface virtual MAC: 00-09-0f-09-00-02
- fabric2 interface virtual MAC: 00-09-0f-09-00-03
- port1 interface virtual MAC: 00-09-0f-09-00-04
- port2 interface virtual MAC: 00-09-0f-09-00-05
- port3 interface virtual MAC: 00-09-0f-09-00-06
- port4 interface virtual MAC: 00-09-0f-09-00-07
- port5 interface virtual MAC: 00-09-0f-09-00-08
- port6 interface virtual MAC: 00-09-0f-09-00-09
- port7 interface virtual MAC: 00-09-0f-09-00-0a
- port8 interface virtual MAC: 00-09-0f-09-00-0b

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use

the following command to view the port1 interface virtual MAC address (Current\_HWaddr) and the port1 permanent MAC address (Permanent\_HWaddr):

```
get hardware nic port1
.
.
.
Current_HWaddr      00:09:0f:09:00:04
Permanent_HWaddr    00:09:0f:71:0a:dc
.
.
.
```

**7. Display the HA configuration (optional).**

```
get system ha
group-id             : 0
group-name           : example3.com
mode                 : a-a
password             : *
hbdev                : "base1" 50 "port4" 50
session-sync-dev     :
route-ttl            : 10
route-wait           : 0
route-hold           : 10
sync-config          : enable
encryption           : disable
authentication       : disable
hb-interval          : 2
hb-lost-threshold    : 20
helo-holddown        : 20
arps                 : 5
arps-interval        : 8
session-pickup       : disable
link-failed-signal   : disable
uninterruptible-upgrade: enable
ha-mgmt-status       : disable
ha-eth-type          : 8890
hc-eth-type          : 8891
l2ep-eth-type        : 8893
subsecond            : disable
vcluster2            : disable
vcluster-id          : 1
override             : disable
priority             : 128
schedule             : round-robin
monitor              :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom                 : "root"
load-balance-all    : disable
```

8. Repeat these steps for the second and third FortiGate units.

Set the second FortiGate unit host name to:

```
config system global
    set hostname 5005_ha_2
end
```

Set the third FortiGate unit host name to:

```
config system global
    set hostname 5005_ha_3
end
```

As you insert and configure each FortiGate unit they will negotiate and join the cluster using the base1 interface for HA heartbeat communication.

### To connect the cluster to the network

1. Connect the port1 interfaces of the cluster to a switch that can connect to the router and the internal network.
2. Connect the port4 interfaces of the cluster units together using a switch.  
These interfaces become the backup heartbeat interface.
3. Connect one of the FortiSwitch-5003A front panel fabric interfaces (for example, F3) to the engineering network.

### To switch the cluster to Transparent mode

1. Log into the cluster CLI.
2. Change to Transparent mode.

```
config system settings
    set opmode transparent
    set manageip 10.22.101.20/24
    set gateway 10.22.101.1
end
```

The cluster switches to Transparent Mode.

You can now connect to the cluster CLI using SSH to connect to the cluster internal interface using the management IP address (10.22.101.20 ).

### To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. To verify the HA status of the cluster unit that you logged into, enter the CLI command `get system status`. Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 5005
  Mode: a-a
  Group: 0
  Debug: 0
  ses_pickup: disable
  load_balance: disable
  schedule: round robin
  Master:128 5005_ha_1          FG5A253E07600124 0
  Slave :128 5005_ha_2          FG5A253E06500088 1
  Slave :128 5005_ha_3          FG5A253E06500099 2
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG5A253E07600124
  Slave :1 FG5A253E06500088
  Slave :2 FG5A253E06500099
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add a password for the admin administrative account

1. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
end
```

## Example: converting a standalone FortiGate unit to a cluster

You can convert an already configured and installed FortiGate unit into a cluster by configuring this FortiGate unit to be a primary unit and then adding subordinate units.

General configuration steps:

- Configure the original FortiGate unit for HA operation.
- Set the HA Device Priority of the original FortiGate unit to 255 to make sure that this FortiGate unit becomes the primary unit after cluster negotiation and synchronization.
- Back up the configuration of the original FortiGate unit.
- Configure one or more new FortiGate units with the same HA configuration as the original FortiGate unit with one exception. Keep the Unit Priority at the default setting, which is 128.
- Connect the FortiGate units to form a cluster and connect the cluster to your network.

When you power on all of the FortiGate units in the cluster, the original FortiGate unit becomes the primary unit. Its configuration is synchronized to all of the subordinate units. The entire

cluster now operates with the original FortiGate unit configuration. No further configuration changes are required.

The new FortiGate units must:

- Have the same hardware configuration as the original FortiGate unit. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the original FortiGate unit.
- Be set to the same operating mode (NAT or Transparent) as the original FortiGate unit.
- Be operating in single VDOM mode.

In addition to one or more new FortiGate units, you need sufficient switches to connect all of the FortiGate interfaces in the cluster. Generally you will need one switch per interface, as it will have to connect that same interface on all cluster units. That is, all port1 interfaces use the port1 switch, port2 interfaces use the port2 switch, and so on. Intelligent switches that can be partitioned can reduce your switch requirements.

Converting a FortiGate unit to a primary unit and adding in the subordinate unit or units results in a brief service interruption as you disconnect and reconnect FortiGate interfaces and as the cluster negotiates. Therefore, conversion should only be done during off peak hours.

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP you will not be able to configure HA.

### To configure the original FortiGate unit for HA operation

1. Connect to the FortiGate unit web-based manager.
2. Go to *System > Config > HA*.
3. Configure the FortiGate unit for HA operation.

<b>Mode</b>	Active-Active
<b>Device Priority</b>	255
<b>Group Name</b>	example4.com
<b>Password</b>	HA_pass_4

You can make other HA configuration changes after the cluster is operating.

4. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)).

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

5. Configure the new FortiGate units with the same HA configuration as the original FortiGate unit. The one exception is to keep the device priorities of the new FortiGate units at 128 to ensure the original FortiGate unit will become the primary unit in the new cluster.

<b>Mode</b>	Active-Active
<b>Device Priority</b>	128
<b>Group Name</b>	example4.com
<b>Password</b>	HA_pass_4

6. Configure the other FortiGate units to the same operation mode as the original FortiGate unit.

There is no need to make any other configuration changes (including network configuration changes) to the other FortiGate units.
7. Optionally power off all of the cluster units.

If you don't power off all of the units they may not negotiate to form a cluster when they are connected together.
8. Connect the cluster to your network.

For example, for a configuration similar to the FortiGate-620B cluster configuration described in this chapter, see [“To connect the cluster to the network” on page 1156](#).
9. Power on all of the cluster units.

As the units start they change their MAC addresses and then negotiate to choose the primary unit and the subordinate units. This negotiation occurs with no user intervention and normally takes less than a minute.

The original the FortiGate unit becomes the primary unit because the device priority of the original FortiGate unit is higher than the device priority of the other FortiGate units. The configuration of the original FortiGate unit is synchronized to all the cluster units. As a result, the cluster is quickly up and running and configured for your network. No further configuration changes are required.

## Example: adding a new unit to an operating cluster

This procedure describes how to add a new FortiGate unit to a functioning cluster. Adding a new unit to a cluster does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the new cluster unit.

You can use this procedure to add as many units as required to the cluster.

### To add a new unit to a functioning cluster

1. Install the same firmware build on the new cluster unit as is running on the cluster.
2. Configure the new cluster unit for HA operation with the same HA configuration as the other units in the cluster.
3. If the cluster is running in Transparent mode, change the operating mode of the new cluster unit to Transparent mode.
4. Connect the new cluster unit to the cluster.
5. For example, for a configuration similar to the FortiGate-620B cluster configuration described in this chapter, see [“To connect the cluster to the network” on page 1156](#).

**6. Power on the new cluster unit.**

When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the new unit configuration with the configuration of the primary unit.

You can add a new unit to a functioning cluster at any time. The new cluster unit must:

- Have the same hardware configuration as the cluster units. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the cluster.
- Be set to the same operating mode (NAT or Transparent) as the cluster.
- Be operating in single VDOM mode.

## Example: replacing a failed cluster unit

This procedure describes how to remove a failed cluster unit from a cluster and add a new one to replace it. You can also use this procedure to remove a failed unit from a cluster, repair it and add it back to the cluster. Replacing a failed does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the replacement unit.

You can use this procedure to replace more than one cluster unit.

### To replace a failed cluster unit

**1. Disconnect the failed unit from the cluster and the network.**

If you maintain other connections between the network and the still functioning cluster unit or units and between remaining cluster units network traffic will continue to be processed.

**2. Repair the failed cluster unit, or obtain a replacement unit with the exact same hardware configuration as the failed cluster unit.**

**3. Install the same firmware build on the repaired or replacement unit as is running on the cluster.**

**4. Configure the repaired or replacement unit for HA operation with the same HA configuration as the cluster.**

**5. If the cluster is running in Transparent mode, change the operating mode of the repaired or replacement cluster unit to Transparent mode.**

**6. Connect the repaired or replacement cluster unit to the cluster.**

For example, for a configuration similar to the FortiGate-620B cluster configuration described in this chapter, see [“To connect the cluster to the network” on page 1156](#).

**7. Power on the repaired or replacement cluster unit.**

When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the repaired or replacement unit configuration with the configuration of the primary unit.

You can add a repaired or replacement unit to a functioning cluster at any time. The repaired or replacement cluster unit must:

- Have the same hardware configuration as the cluster units. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the cluster.
- Be set to the same operating mode (NAT or Transparent) as the cluster.
- Be operating in single VDOM mode.

## Example: HA and 802.3ad aggregated interfaces

On FortiGate models that support it you can use 802.3ad link aggregation to combine two or more interfaces into a single aggregated interface. 802.3ad Link Aggregation and its management protocol, Link Aggregation Control Protocol (LACP) are a method for combining multiple physical links into a single logical link. This increases both potential throughput and network resiliency. Using LACP, traffic is distributed among the physical interfaces in the link, potentially resulting in increased performance.

This example describes how to configure an HA cluster consisting of two FortiGate-620B units with two aggregated 1000 Mb connections to the Internet using port1 and port2 and two aggregated 1000 Mb connections to the internal network using port3 and port4. The aggregated interfaces are also configured as HA monitored interfaces.

Each of the aggregate links connects to a different switch. Each switch is configured for link aggregation (2x1000Mb).

**Figure 195:**Example cluster with aggregate interfaces

### HA interface monitoring, link failover, and 802.3ad aggregation

When monitoring the aggregated interface, HA interface monitoring treats the aggregated link as a single interface and does not monitor the individual physical interfaces in the link. HA interface monitoring registers the link to have failed only if all the physical interfaces in the link have failed. If only some of the physical interfaces in the link fail or become disconnected, HA considers the link to be operating normally.

### HA MAC addresses and 802.3ad aggregation

If a configuration uses the Link Aggregate Control Protocol (LACP) (either passive or active), LACP is negotiated over all of the interfaces in any link. For a standalone FortiGate unit, the FortiGate LACP implementation uses the MAC address of the first interface in the link to uniquely identify that link. For example, a link consisting of port1 and port2 interfaces would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. An aggregate interface in a cluster acquires the virtual MAC address that would have been acquired by the first interface in the aggregate.

## Link aggregation, HA failover performance, and HA mode

To operate an active-active or active-passive cluster with aggregated interfaces and for best performance of a cluster with aggregated interfaces, the switches used to connect the cluster unit aggregated interfaces together should support configuring multiple Link Aggregation (LAG) groups.

For example, the cluster shown in [Figure 195](#) should be configured into two LAG groups on the external switch: one for the port1 and port2 aggregated interface of 620\_ha\_1 and a second one for the port1 and port2 aggregate interface of 620\_ha\_2. You should also be able to do the same on the internal switch for the port3 and port4 aggregated interfaces of each cluster unit.

As a result, the subordinate unit aggregated interfaces would participate in LACP negotiation while the cluster is operating. In an active-active mode cluster, packets could be redirected to the subordinate unit interfaces. As well, in active-active or active-passive mode, after a failover the subordinate unit can become a primary unit without having to perform LACP negotiation before it can process traffic. Performing LACP negotiation causes a minor failover delay.

However if you cannot configure multiple LAG groups on the switches, due to the primary and subordinate unit interfaces having the same MAC address, the switch will put all of the interfaces into the same LAG group which would disrupt the functioning of the cluster. To prevent this from happening, you must change the FortiGate aggregated interface configuration to prevent subordinate units from participating in LACP negotiation.

For example, use the following command to prevent subordinate units from participating in LACP negotiation with an aggregate interface named Port1\_Port2:

```
config system interface
    edit Port1_Port2
        set lacp-ha-slave disable
    end
```

As a result of this setting, subordinate unit aggregated interfaces cannot accept packets. This means that you cannot operate the cluster in active-active mode because in active-active mode the subordinate units must be able to receive and process packets. Also, failover may take longer because after a failover the subordinate unit has to perform LACP negotiation before being able to process network traffic.

Also, it may also be necessary to configure the switch to use Passive or even Static mode for LACP to prevent the switch from sending packets to the subordinate unit interfaces, which won't be able to process them.

Finally, in some cases depending on the LACP configuration of the switches, you may experience delayed failover if the FortiGate LACP configuration is not compatible with the switch LACP configuration. For example, in some cases setting the FortiGate LACP mode to static reduces the failover delay because the FortiGate unit does not perform LACP negotiation. However there is a potential problem with this configuration because static LACP does not send periodic LAC Protocol Data Unit (LACPDU) packets to test the connections. So a non-physical failure (for example, if a device is not responding because its too busy) may not be detected and packets could be lost or delayed.

## General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

### General configuration steps

1. Configure the FortiGate units for HA operation.

- Change each unit's host name.
  - Configure HA.
2. Connect the cluster to the network.
  3. View cluster status.
  4. Add basic configuration settings and configure the aggregated interfaces.
    - Add a password for the admin administrative account.
    - Add the aggregated interfaces.
    - Disable `lACP-ha-slave` so that the subordinate unit does not send LACP packets.
    - Add a default route.

You could also configure aggregated interfaces in each FortiGate unit before the units form a cluster.

5. Configure HA port monitoring for the aggregated interfaces.

## Configuring active-passive HA cluster that includes aggregated interfaces - web-based manager

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

### To configure the FortiGate-620B units for HA operation

1. Power on the first FortiGate-620B unit and log into the web-based manager.
2. On the *System Information* dashboard widget, beside *Host Name* select *Change*.
3. Enter a new Host Name for this FortiGate unit.

<b>New Name</b>	620_ha_1
-----------------	----------

4. Select OK.
5. Go to *System > Config > HA* and change the following settings.

Mode	Active-Passive	
Group Name	example5.com	
Password	HA_pass_5	
Heartbeat Interface		
	Enable	Priority
port5	Select	50
port6	Select	50

Since port3 and port4 will be used for a aggregated interface, you must change the HA heartbeat configuration to not use those interfaces.

6. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate unit.
8. Repeat these steps for the second FortiGate unit.

Set the second FortiGate unit host name to:

<b>New Name</b>	620_ha_2
-----------------	----------

### To connect the cluster to the network

1. Connect the port1 and port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.

Configure the switch so that the port1 and port2 of 620\_ha\_1 make up an aggregated interface and port1 and port2 of 620\_ha\_2 make up a second aggregated interface.

2. Connect the port3 and port4 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.

Configure the switch so that the port3 and port4 of 620\_ha\_1 make up an aggregated interface and port3 and port4 of 620\_ha\_2 make up another aggregated interface.

3. Connect the port5 interfaces of 620\_ha\_1 and 620\_ha\_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5. Power on the cluster units.

The units negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete, the cluster is ready to be configured for your network.

### To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

The System Information dashboard widget shows the *Cluster Name* (example5.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

2. Go to *System > Config > HA* to view the cluster members list.

The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster web-based manager.
2. Go to *System > Admin > Administrators*.
3. For *admin*, select the *Change Password* icon.
4. Enter and confirm a new password.
5. Select OK.
6. Go to *Router > Static > Static Routes* and temporarily delete the default route.  
You cannot add an interface to a aggregated interface if any settings (such as the default route) are configured for it.
7. Go to *System > Network > Interfaces* and select *Create New* to add the aggregate interface to connect to the Internet.

8. Set *Type* to *802.3ad Aggregate* and configure the aggregate interface to be connected to the Internet:

<b>Name</b>	Port1_Port2
<b>Physical Interface Members</b>	
<b>Selected Interfaces</b>	port1, port2
<b>IP/Netmask</b>	172.20.120.141/24

9. Select OK.

10. Select *Create New* to add the aggregate interface to connect to the internal network.

11. Set *Type* to *802.3ad Aggregate* and configure the aggregate interface to be connected to the Internet:

<b>Name</b>	Port3_Port4
<b>Physical Interface Members</b>	
<b>Selected Interfaces</b>	port3, port4
<b>IP/Netmask</b>	10.11.101.100/24
<b>Administrative Access</b>	HTTPS, PING, SSH

12. Select OK.

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12

- port9 interface virtual MAC: 00-09-0f-09-00-13

13. Connect to the CLI and enter the following command to disable sending LACP packets from the subordinate unit:

```
config system interface
    edit Port1_Port2
        set lacp-ha-slave disable
    next
    edit Port3_Port4
        set lacp-ha-slave disable
end
```

14. Go to *Router > Static > Static Routes*.

15. Add the default route.

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Gateway</b>	172.20.120.2
<b>Device</b>	Port1_Port2
<b>Distance</b>	10

16. Select OK.

#### To configure HA port monitoring for the aggregate interfaces

1. Go to *System > Config > HA*.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the aggregate interfaces:

Port Monitor	
<b>Port1_Port2</b>	Select
<b>Port3_Port4</b>	Select

4. Select OK.

## Configuring active-passive HA cluster that includes aggregate interfaces - CLI

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

#### To configure the FortiGate-620B units for HA operation

1. Power on the first FortiGate-620B unit and log into the CLI.
2. Change the host name for this FortiGate unit:

```
config system global
    set hostname 620_ha_1
end
```

### 3. Configure HA settings.

```
config system ha
    set mode a-p
    set group-name example5.com
    set password HA_pass_5
    set hbdev port5 50 port6 50
end
```

Since port3 and port4 will be used for an aggregated interface, you must change the HA heartbeat configuration.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use

the following command to view the port1 interface virtual MAC address (Current\_HWaddr) and the port1 permanent MAC address (Permanent\_HWaddr):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

**4. Display the HA configuration (optional).**

```
get system ha
group-id          : 0
group-name        : example5.com
mode              : a-p
password          : *
hbdev             : "port5" 50 "port6" 50
session-sync-dev  :
route-ttl         : 10
route-wait        : 0
route-hold        : 10
sync-config       : enable
encryption        : disable
authentication    : disable
hb-interval       : 2
hb-lost-threshold : 20
helo-holddown     : 20
arps              : 5
arps-interval     : 8
session-pickup    : disable
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status    : disable
ha-eth-type       : 8890
hc-eth-type       : 8891
l2ep-eth-type     : 8893
subsecond         : disable
vcluster2         : disable
vcluster-id       : 1
override          : disable
priority          : 128
monitor           :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom              : "root"
```

5. Repeat these steps for the other FortiGate unit.

Set the other FortiGate unit host name to:

```
config system global
    set hostname 620_ha_2
end
```

### To connect the cluster to the network

1. Connect the port1 and port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.

Configure the switch so that the port1 and port2 of 620\_ha\_1 make up an aggregated interface and port1 and port2 of 620\_ha\_2 make up another aggregated interface.

2. Connect the port3 and port4 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.

Configure the switch so that the port3 and port4 of 620\_ha\_1 make up an interfaced and port3 and port4 of 620\_ha\_2 make up another aggregated interface.

3. Connect the port5 interfaces of 620\_ha\_1 and 620\_ha\_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

### To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into. Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 620
  Mode: a-a
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2          FG600B3908600825 0
  Slave :128 620_ha_1          FG600B3908600705 1
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings and the aggregate interfaces.

1. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
  end
```

2. Temporarily delete the default route.

You cannot add an interface to an aggregate interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```
config router static
  delete 1
end
```

### 3. Add the aggregate interfaces:

```
config system interface
    edit Port1_Port2
        set type aggregate
        set lacp-ha-slave disable
        set member port1 port2
        set ip 172.20.120.141/24
        set vdom root
    next
    edit Port3_Port4
        set type aggregate
        set lacp-ha-slave disable
        set member port3 port4
        set ip 10.11.101.100/24
        set vdom root
end
```

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

### 4. Add the default route.

```
config router static
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set gateway 172.20.120.2
        set device Port1_Port2
    end
```

## To configure HA port monitoring for the aggregate interfaces

1. Configure HA port monitoring for the aggregate interfaces.

```
config system ha
    set monitor Port1_Port2 Port3_Port4
end
```

## Example: HA and redundant interfaces

On FortiGate models that support it you can combine two or more interfaces into a single redundant interface. A redundant interface consists of two or more physical interfaces. Traffic is processed by the first physical interface in the redundant interface. If that physical interface fails, traffic fails over to the next physical interface. Redundant interfaces don't have the benefit of improved performance that aggregate interfaces can have, but they do provide failover if a physical interface fails or is disconnected.

**Figure 196:**Example cluster with a redundant interfaces

This example describes how to configure an HA cluster consisting of two FortiGate-620B units with a redundant interface connection to the Internet and to an internal network. The connection to the Internet uses port1 and port2. The connection to the internal network uses port3 and port4. The HA heartbeat uses port5 and port6.

The redundant interfaces are also configured as HA monitored interfaces.

## HA interface monitoring, link failover, and redundant interfaces

HA interface monitoring monitors the redundant interface as a single interface and does not monitor the individual physical interfaces in the redundant interface. HA interface monitoring registers the redundant interface to have failed only if all the physical interfaces in the redundant interface have failed. If only some of the physical interfaces in the redundant interface fail or become disconnected, HA considers the redundant interface to be operating normally.

## HA MAC addresses and redundant interfaces

For a standalone FortiGate unit a redundant interface has the MAC address of the first physical interface added to the redundant interface configuration. A redundant interface consisting of port1 and port2 would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. A redundant interface in a cluster acquires the virtual MAC address that would have been acquired by the first physical interface added to the redundant interface configuration.

## Connecting multiple redundant interfaces to one switch while operating in active-passive HA mode

HA assigns the same virtual MAC addresses to the subordinate unit interfaces as are assigned to the corresponding primary unit interfaces. Consider a cluster of two FortiGate units operating in active-passive mode with a redundant interface consisting of port1 and port2. You can connect multiple redundant interfaces to the same switch if you configure the switch so that it defines multiple separate redundant interfaces and puts the redundant interfaces of each cluster unit into separate redundant interfaces. In this configuration, each cluster unit forms a separate redundant interface with the switch.

However, if the switch is configured with a single four-port redundant interface configuration, because the same MAC addresses are being used by both cluster units, the switch adds all four interfaces (port1 and port2 from the primary unit and port1 and port2 from the subordinate unit) to the same redundant interface.

To avoid unpredictable results, when you connect a switch to multiple redundant interfaces in an active-passive cluster you should configure separate redundant interfaces on the switch; one for each cluster unit.

## Connecting multiple redundant interfaces to one switch while operating in active-active HA mode

In an active-active cluster, all cluster units send and receive packets. To operate a cluster with redundant interfaces in active-active mode, with multiple redundant interfaces connected to the same switch, you must separate the redundant interfaces of each cluster unit into different redundant interfaces on the connecting switch.

## General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

### General configuration steps

1. Configure the FortiGate units for HA operation.
  - Change each unit's host name.
  - Configure HA.
2. Connect the cluster to the network.
3. View cluster status.
4. Add basic configuration settings and configure the redundant interfaces.
  - Add a password for the admin administrative account.
  - Add the redundant interfaces.

- Add a default route.

You could also configure redundant interfaces in each FortiGate unit before they form a cluster.

5. Configure HA port monitoring for the redundant interfaces.

## Configuring active-passive HA cluster that includes redundant interfaces - web-based manager

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

### To configure the FortiGate-620B units for HA operation

1. Power on the first FortiGate-620B unit and log into the web-based manager.
2. On the *System Information* dashboard widget, beside *Host Name* select *Change*.
3. Enter a new Host Name for this FortiGate unit.

<b>New Name</b>	620_ha_1
-----------------	----------

4. Select OK.
5. Go to *System > Config > HA* and change the following settings.

<b>Mode</b>	Active-Passive
-------------	----------------

<b>Group Name</b>	example6.com
-------------------	--------------

<b>Password</b>	HA_pass_6
-----------------	-----------

#### Heartbeat Interface

	Enable	Priority
<b>port5</b>	Select	50
<b>port6</b>	Select	50

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

6. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07

- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate unit.
8. Repeat these steps for the second FortiGate unit.  
Set the second FortiGate unit host name to:

---

<b>New Name</b>	620_ha_2
-----------------	----------

---

### To connect the cluster to the network

1. Connect the port1 and port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.  
Configure the switch so that the port1 and port2 of 620\_ha\_1 make up a redundant interface and port1 and port2 of 620\_ha\_2 make up another redundant interface.
2. Connect the port3 and port4 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.  
Configure the switch so that the port3 and port4 of 620\_ha\_1 make up a redundant interface and port3 and port4 of 620\_ha\_2 make up another redundant interface.
3. Connect the port5 interfaces of 620\_ha\_1 and 620\_ha\_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

### To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

The System Information dashboard widget shows the *Cluster Name* (example5.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

2. Go to *System > Config > HA* to view the cluster members list.

The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

### To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster web-based manager.
2. Go to *System > Admin > Administrators*.
3. For *admin*, select the *Change Password* icon
4. Enter and confirm a new password.
5. Select OK.
6. Go to *Router > Static > Static Routes* and temporarily delete the default route.  
You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.
7. Go to *System > Network > Interfaces* and select *Create New* to add the redundant interface to connect to the Internet.
8. Set *Type* to *Redundant Interface* and configure the redundant interface to be connected to the Internet:

<b>Name</b>	Port1_Port2
<b>Physical Interface Members</b>	
<b>Selected Interfaces</b>	port1, port2
<b>IP/Netmask</b>	172.20.120.141/24

9. Select OK.
10. Select *Create New* to add the redundant interface to connect to the internal network.

11. Set *Type* to *Redundant Interface* and configure the redundant interface to be connected to the Internet:

<b>Name</b>	Port3_Port4
<b>Physical Interface Members</b>	
<b>Selected Interfaces</b>	port3, port4
<b>IP/Netmask</b>	10.11.101.100/24
<b>Administrative Access</b>	HTTPS, PING, SSH

12. Select OK.

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

13. Go to *Router > Static > Static Routes*.

14. Add the default route.

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Gateway</b>	172.20.120.2
<b>Device</b>	Port1_Port2
<b>Distance</b>	10

15. Select OK.

### To configure HA port monitoring for the redundant interfaces

1. Go to *System > Config > HA*.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the redundant interfaces:

Port Monitor	
Port1_Port2	Select
Port3_Port4	Select

4. Select OK.

## Configuring active-passive HA cluster that includes redundant interfaces - CLI

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

### To configure the FortiGate-620B units for HA operation

1. Power on the first FortiGate-620B unit and log into the CLI.
2. Change the host name for this FortiGate unit:

```
config system global
    set hostname 620_ha_1
end
```

3. Configure HA settings.

```
config system ha
    set mode a-p
    set group-name example6.com
    set password HA_pass_6
    set hbdev port5 50 port6 50
end
```

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a

- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

**4. Display the HA configuration (optional).**

```
get system ha
group-id          : 0
group-name        : example6.com
mode              : a-p
password          : *
hbdev             : "port5" 50 "port6" 50
session-sync-dev  :
route-ttl         : 10
route-wait        : 0
route-hold        : 10
sync-config       : enable
encryption        : disable
authentication    : disable
hb-interval       : 2
hb-lost-threshold : 20
helo-holddown     : 20
arps              : 5
arps-interval     : 8
session-pickup    : disable
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status    : disable
ha-eth-type       : 8890
hc-eth-type       : 8891
l2ep-eth-type     : 8893
subsecond         : disable
vcluster2         : disable
vcluster-id       : 1
override          : disable
priority          : 128
monitor           :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom              : "root"
```

**5. Repeat these steps for the other FortiGate unit.**

Set the other FortiGate unit host name to:

```
config system global
    set hostname 620_ha_2
end
```

**To connect the cluster to the network**

1. Connect the port1 and port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.

Configure the switch so that the port1 and port2 of 620\_ha\_1 make up a redundant interface and port1 and port2 of 620\_ha\_2 make up another redundant interface.

2. Connect the port3 and port4 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.  
Configure the switch so that the port3 and port4 of 620\_ha\_1 make up a redundant interface and port3 and port4 of 620\_ha\_2 make up another redundant interface.
3. Connect the port5 interfaces of 620\_ha\_1 and 620\_ha\_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.  
The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.  
When negotiation is complete the cluster is ready to be configured for your network.

### To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into. Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
Model: 620
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
Master:128 620_ha_2          FG600B3908600825 0
Slave :128 620_ha_1          FG600B3908600705 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

### To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

## To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings and the redundant interfaces.

1. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswr>
  end
```

2. Temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```
config router static
  delete 1
end
```

### 3. Add the redundant interfaces:

```
config system interface
    edit Port1_Port2
        set type redundant
        set member port1 port2
        set ip 172.20.120.141/24
        set vdom root
    next
    edit Port3_Port4
        set type redundant
        set member port3 port4
        set ip 10.11.101.100/24
        set vdom root
end
```

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

### 4. Add the default route.

```
config router static
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set gateway 172.20.120.2
        set device Port1_Port2
    end
```

### To configure HA port monitoring for the redundant interfaces

1. Configure HA port monitoring for the redundant interfaces.

```
config system ha
    set monitor Port1_Port2 Port3_Port4
end
```

## Troubleshooting HA clusters

This section describes some HA clustering troubleshooting techniques.

### Ignoring hardware revisions

Some FortiGate platforms have gone through multiple hardware versions. In some cases the hardware changes between versions have meant that by default you cannot form a cluster if the FortiGate units in the cluster have different hardware versions. If you run into this problem you can use the following command on each FortiGate unit to cause the cluster to ignore different hardware versions:

```
execute ha ignore-hardware-revision {disable | enable | status}
```

This command is only available on FortiGate units that have had multiple hardware revisions. By default the command is set to prevent FortiOS from forming clusters between FortiGate units with different hardware revisions. You can enable this command to be able to create a cluster consisting of FortiGate units with different hardware revisions. Use the `status` option to verify the whether ignoring hardware revisions is enabled or disabled.

Affected hardware models include:

- FortiGate-100D
- FortiGate-300C
- FortiGate-80C and FortiWiFi-80C
- FortiGate-60C

### Before you set up a cluster

Before you set up a cluster ask yourself the following questions about the FortiGate units that you are planning to use to create a cluster.

1. Do all the FortiGate units have the same hardware configuration? Including the same hard disk configuration and the same AMC cards installed in the same slots?
2. Do all FortiGate units have the same firmware build?
3. Are all FortiGate units set to the same operating mode (NAT or Transparent)?
4. Are all the FortiGate units operating in single VDOM mode?
5. If the FortiGate units are operating in multiple VDOM mode do they all have the same VDOM configuration?

In some cases you may be able to form a cluster if different FortiGate units have different firmware builds, different VDOM configurations, and are in different operating modes. However, if you encounter problems they may be resolved by installing the same firmware build on each unit, and give them the same VDOM configuration and operating mode.

---

## Troubleshooting the initial cluster configuration

This section describes how to check a cluster when it first starts up to make sure that it is configured and operating correctly. This section assumes you have already configured your HA cluster.

### To verify that a cluster can process traffic and react to a failure

1. Add a basic security policy configuration and send network traffic through the cluster to confirm connectivity.

For example, if the cluster is installed between the Internet and an internal network, set up a basic internal to external security policy that accepts all traffic. Then from a PC on the internal network, browse to a website on the Internet or ping a server on the Internet to confirm connectivity.

2. From your management PC, set ping to continuously ping the cluster, and then start a large download, or in some other way establish ongoing traffic through the cluster.
3. While traffic is going through the cluster, disconnect the power from one of the cluster units.

You could also shut down or restart a cluster unit.

Traffic should continue with minimal interruption.

4. Start up the cluster unit that you disconnected.

The unit should re-join the cluster with little or no affect on traffic.

5. Disconnect a cable for one of the HA heartbeat interfaces.

The cluster should keep functioning, using the other HA heartbeat interface.

6. If you have port monitoring enabled, disconnect a network cable from a monitored interface.

Traffic should continue with minimal interruption.

### To verify the cluster configuration - web-based manager

1. Log into the cluster web-based manager.
2. Check the system dashboard to verify that the System Information widget displays all of the cluster units.
3. Check the cluster member graphic to verify that the correct cluster unit interfaces are connected.
4. Go to *System > Config > HA* and verify that all of the cluster units are displayed on the cluster members list.
5. From the cluster members list, edit the primary unit (master) and verify the cluster configuration is as expected.

### To troubleshoot the cluster configuration - web-based manager

1. Connect to each cluster unit web-based manager and verify that the HA configurations are the same.
2. To connect to each web-based manager, you may need to disconnect some units from the network to connect to the other if the units have the same IP address.
3. If the configurations are the same, try re-entering the cluster *Password* on each cluster unit in case you made an error typing the password when configuring one of the cluster units.
4. Check that the correct interfaces of each cluster unit are connected.

Check the cables and interface LEDs.

Use the Unit Operation dashboard widget, system network interface list, or cluster members list to verify that each interface that should be connected actually is connected.

If Link is down re-verify the physical connection. Try replacing network cables or switches as required.

## To verify the cluster configuration - CLI

1. Log into each cluster unit CLI.

You can use the console connection if you need to avoid the problem of units having the same IP address.

2. Enter the command `get system status`.

Look for the following information in the command output.

Current HA mode: a-a, master	The cluster units are operating as a cluster and you have connected to the primary unit.
Current HA mode: a-a, backup	The cluster units are operating as a cluster and you have connected to a subordinate unit.
Current HA mode: standalone	The cluster unit is not operating in HA mode

3. Verify that the `get system ha status` command displays all of the cluster units.
4. Enter the `get system ha` command to verify that the HA configuration is correct and the same for each cluster unit.

## To troubleshoot the cluster configuration - CLI

1. Try using the following command to re-enter the cluster password on each cluster unit in case you made an error typing the password when configuring one of the cluster units.

```
config system ha
    set password <password>
end
```

2. Check that the correct interfaces of each cluster unit are connected.

Check the cables and interface LEDs.

Use `get hardware nic <interface_name>` command to confirm that each interface is connected. If the interface is connected the command output should contain a `Link: up` entry similar to the following:

```
get hardware nic port1
.
.
.
Link: up
.
.
.
```

If Link is down, re-verify the physical connection. Try replacing network cables or switches as required.

## More troubleshooting information

Much of the information in this HA guide can be useful for troubleshooting HA clusters. Here are some links to sections with more information.

- If sessions are lost after a failover you may need to change route-ttl to keep synchronized routes active longer. See [“Change how long routes stay in a cluster unit routing table” on page 1317](#).
- To control which cluster unit becomes the primary unit, you can change the device priority and enable override. See [“Controlling primary unit selection using device priority and override” on page 1140](#).
- Changes made to a cluster can be lost if override is enabled. See [“Configuration changes can be lost if override is enabled” on page 1141](#).
- In some cases, age differences among cluster units result in the wrong cluster unit becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units. You can resolve this problem by resetting the age of one or more cluster units. See [“Resetting the age of all cluster units” on page 1135](#). You can also adjust how sensitive the cluster is to age differences. This can be useful if large age differences cause problems. See [“Cluster age difference margin \(grace period\)” on page 1133](#) and [“Changing the cluster age difference margin” on page 1133](#).
- If one of the cluster units needs to be serviced or removed from the cluster for other reasons, you can do so without affecting the operation of the cluster. See [“Disconnecting a cluster unit from a cluster” on page 1285](#).
- The web-based manager and CLI will not allow you to configure HA if:
- You have configured a FortiGate interface to get its IP address using DHCP or PPPoE. See [“FortiGate HA compatibility with PPPoE and DHCP” on page 1142](#).
- You have enabled VRRP. See [“VRRP” on page 1364](#).
- You have enabled TCP session synchronization. See [“FortiGate Session Life Support Protocol \(FGSP\)” on page 1370](#).
- Some third-party network equipment may prevent HA heartbeat communication, resulting in a failure of the cluster or the creation of a split brain scenario. For example, some switches use packets with the same Ethertype as HA heartbeat packets use for internal functions and when used for HA heartbeat communication the switch generates CRC errors and the packets are not forwarded. See [“Heartbeat packet Ethernets” on page 1297](#).
- Very busy clusters may not be able to send HA heartbeat packets quickly enough, also resulting in a split brain scenario. You may be able to resolve this problem by modifying HA heartbeat timing. See [“Modifying heartbeat timing” on page 1298](#).
- Very busy clusters may suffer performance reductions if session pickup is enabled. If possible you can disable this feature to improve performance. If you require session pickup for your cluster, several options are available for improving session pickup performance. See [“Improving session synchronization performance” on page 1331](#).
- If it takes longer than expected for a cluster to failover you can try changing how the primary unit sends gratuitous ARP packets. See [“Changing how the primary unit sends gratuitous ARP packets after a failover” on page 1301](#).
- You can also improve failover times by configuring the cluster for subsecond failover. See [“Subsecond failover” on page 1324](#) and [“Failover performance” on page 1340](#).
- When you first put a FortiGate unit in HA mode you may lose connectivity to the unit. This occurs because HA changes the MAC addresses of all FortiGate unit interfaces, including the one that you are connecting to. The cluster MAC addresses also change if you change the some HA settings such as the cluster group ID. The connection will be restored in a short time as your network and PC updates to the new MAC address. To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the

FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

- Since HA changes all cluster unit MAC addresses, if your network uses MAC address filtering you may have to make configuration changes to account for the HA MAC addresses.
- A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID. See [“Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain” on page 1305](#).
- The cluster CLI displays `slave is not in sync` messages if there is a synchronization problem between the primary unit and one or more subordinate units. See [“How to diagnose HA out of sync messages” on page 1313](#).
- If you have configured dynamic routing and the new primary unit takes too long to update its routing table after a failover you can configure graceful restart and also optimize how routing updates are synchronized. See [“Configuring graceful restart for dynamic routing failover” on page 1315](#) and [“Controlling how the FGCP synchronizes kernel routing table updates” on page 1316](#).
- Some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur after a link failover if the switch does not detect the failure and does not clear its MAC forwarding table. See [“Updating MAC forwarding tables when a link failover occurs” on page 1323](#).
- If a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails you can enable remote link failover to maintain communication. See [“Remote link failover” on page 1325](#).
- If you find that some cluster units are not running the same firmware build you can reinstall the correct firmware build on the cluster to upgrade all cluster units to the same firmware build. See [“Synchronizing the firmware build running on a new cluster unit” on page 1275](#).

# Virtual clusters

This chapter provides an introduction to virtual clustering and also contains general procedures and configuration examples that describe how to configure FortiGate HA virtual clustering.

This chapter contains the following sections:

- [Virtual clustering overview](#)
- [Configuring HA for virtual clustering](#)
- [Example: virtual clustering with two VDOMs and VDOM partitioning](#)
- [Example: inter-VDOM links in a virtual clustering configuration](#)
- [Troubleshooting virtual clustering](#)

## Virtual clustering overview

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

[Figure](#) shows an example virtual cluster configuration consisting of two FortiGate-620B units. The virtual cluster has two virtual domains, root and Eng\_vdm.

The root virtual domain includes the port1 and port2 interfaces. The Eng\_vdm virtual domain includes the port5 and port6 interfaces. The port3 and port4 interfaces (not shown in the diagram) are the HA heartbeat interfaces.

FortiGate virtual clustering is limited to a cluster of 2 FortiGate units with multiple VDOMs enabled. If you want to create a cluster of more than 2 FortiGate units operating with multiple VDOMS you could consider other solutions that either do not include multiple VDOMs in one cluster or employ a feature such as standalone session synchronization. See [“FortiGate Session Life Support Protocol \(FGSP\)” on page 1370](#).

## Virtual clustering and failover protection

Virtual clustering operates on a cluster of two (and only two) FortiGate units with VDOMs enabled. Each VDOM creates a cluster between instances of the VDOMs on the two FortiGate units in the virtual cluster. All traffic to and from the VDOM stays within the VDOM and is processed by the VDOM. One cluster unit is the primary unit for each VDOM and one cluster unit is the subordinate unit for each VDOM. The primary unit processes all traffic for the VDOM. The subordinate unit does not process traffic for the VDOM. If a cluster unit fails, all traffic fails over to the cluster unit that is still operating.

## Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You do not have to add a heartbeat interface for each VDOM.

**Figure 197:**Example virtual cluster of two FortiGate-620B units

## Virtual clustering and HA override

For a virtual cluster configuration, override is enabled by default for both virtual clusters when you:

- Enable VDOM partitioning from the web-based manager by moving virtual domains to virtual cluster 2
- Enter `set vcluster2 enable` from the CLI `config system ha` command to enable virtual cluster 2.

Usually you would enable virtual cluster 2 and expect one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. For this distribution to occur override must be enabled for both virtual clusters. Otherwise you will need to restart the cluster to force it to renegotiate.

If override is enabled the cluster may renegotiate too often. You can choose to disable override at any time. If you decide to disable override, for best results, you should disable it for both cluster units.

For more information about HA override see [“HA override” on page 1138](#).

## Virtual clustering and load balancing or VDOM partitioning

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary unit receives all sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

In a VDOM partitioning virtual clustering configuration, the HA mode is set to active-passive. Even though virtual clustering operates in active-passive mode you can configure a form of load balancing by using VDOM partitioning to distribute traffic between both cluster units. To configure VDOM partitioning you set one cluster unit as the primary unit for some virtual

domains and you set the other cluster unit as the primary unit for other virtual domains. All traffic for a virtual domain is processed by the primary unit for that virtual domain. You can control the distribution of traffic between the cluster units by adjusting which cluster unit is the primary unit for each virtual domain.

For example, you could have 4 VDOMs, two of which have a high traffic volume and two of which have a low traffic volume. You can configure each cluster unit to be the primary unit for one of the high volume VDOMs and one of the low volume VDOMs. As a result each cluster unit will be processing traffic for a high volume VDOM and a low volume VDOM, resulting in an even distribution of traffic between the cluster units. You can adjust the distribution at any time. For example, if a low volume VDOM becomes a high volume VDOM you can move it from one cluster unit to another until the best balance is achieved.

From the web-based manager you configure VDOM partitioning by setting the HA mode to active-passive and distributing virtual domains between Virtual Cluster 1 and Virtual Cluster 2. You can also configure different device priorities, port monitoring, and remote link failover, for Virtual Cluster 1 and Virtual Cluster 2.

The device priorities for virtual cluster 1 and virtual cluster 2 are not synchronized between the FortiGate units in the virtual cluster. You must configure these device priorities separately for each cluster unit.

---

From the CLI you configure VDOM partitioning by setting the HA mode to `a-p`. Then you configure device priority, port monitoring, and remote link failover and specify the VDOMs to include in virtual cluster 1. You do the same for virtual cluster 2 by entering the `config secondary-vcluster` command.

Failover protection does not change. If one cluster unit fails, all sessions are processed by the remaining cluster unit. No traffic interruption occurs for the virtual domains for which the still functioning cluster unit was the primary unit. Traffic may be interrupted temporarily for virtual domains for which the failed unit was the primary unit while processing fails over to the still functioning cluster unit.

If the failed cluster unit restarts and rejoins the virtual cluster, VDOM partitioning load balancing is restored.

## Configuring HA for virtual clustering

If your cluster uses VDOMs, you are configuring virtual clustering. Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below.

To configure HA options for a cluster with VDOMs enabled:

- Log into the global web-based manager and go to *System > Config > HA*.
- From the CLI, log into the Global Configuration:

The following example shows how to configure active-active virtual clustering:

```
config global
    config system ha
        set mode a-a
        set group-name vexample1.com
        set password vHA_pass_1
    end
end
```

The following example shows how to configure active-passive virtual clustering:

```
config global
    config system ha
        set mode a-p
        set group-name vexample1.com
        set password vHA_pass_1
    end
end
```

The following example shows how to configure VDOM partitioning for virtual clustering. In the example, the FortiGate unit is configured with three VDOMs (domain\_1, domain\_2, and domain\_3) in addition to the root VDOM. The example shows how to set up a basic HA configuration that sets the device priority of virtual cluster 1 to 200. The example also shows how to enable `vcluster2`, how to set the device priority of virtual cluster 2 to 100 and how to add the virtual domains `domain_2` and `domain_3` to virtual cluster 2.

When you enable multiple VDOMs, `vcluster2` is enabled by default. Even so the command to enable `vcluster2` is included in this example in case for some reason it has been disabled. When `vcluster2` is enabled, `override` is also enabled.

The result of this configuration would be that the cluster unit that you are logged into becomes the primary unit for virtual cluster 1. This cluster unit processes all traffic for the root and `domain_1` virtual domains.

```
config global
    config system ha
        set mode a-p
        set group-name vexample1.com
        set password vHA_pass_1
        set priority 200
        set vcluster2 enable
        config secondary-vcluster
            set vdom domain_2 domain_3
            set priority 100
        end
    end
end
```

The following example shows how to use the `execute ha manage` command to change the device priorities for virtual cluster 1 and virtual cluster 2 for the other unit in the cluster. The commands set the device priority of virtual cluster 1 to 100 and virtual cluster 2 to 200.

The result of this configuration would be that the other cluster unit becomes the primary unit for virtual cluster 2. This other cluster unit would process all traffic for the domain\_2 and domain\_3 virtual domains.

```
config global
  execute ha manage 1
  config system ha
    set priority 100
    set vcluster2 enable
    config secondary-vcluster
      set priority 200
    end
  end
end
end
end
```

## Example: virtual clustering with two VDOMs and VDOM partitioning

This section describes how to configure the example virtual clustering configuration shown in [Figure 198](#). This configuration includes two virtual domains, root and Eng\_vdm and includes VDOM partitioning that sends all root VDOM traffic to 620\_ha\_1 and all Eng\_vdm VDOM traffic to 620\_ha\_2. The traffic from the internal network and the engineering network is distributed between the two FortiGate units in the virtual cluster. If one of the cluster units fails, the remaining unit will process traffic for both VDOMs.

The procedures in this example describe some of many possible sequences of steps for configuring virtual clustering. For simplicity many of these procedures assume that you are starting with new FortiGate units set to the factory default configuration. However, this is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

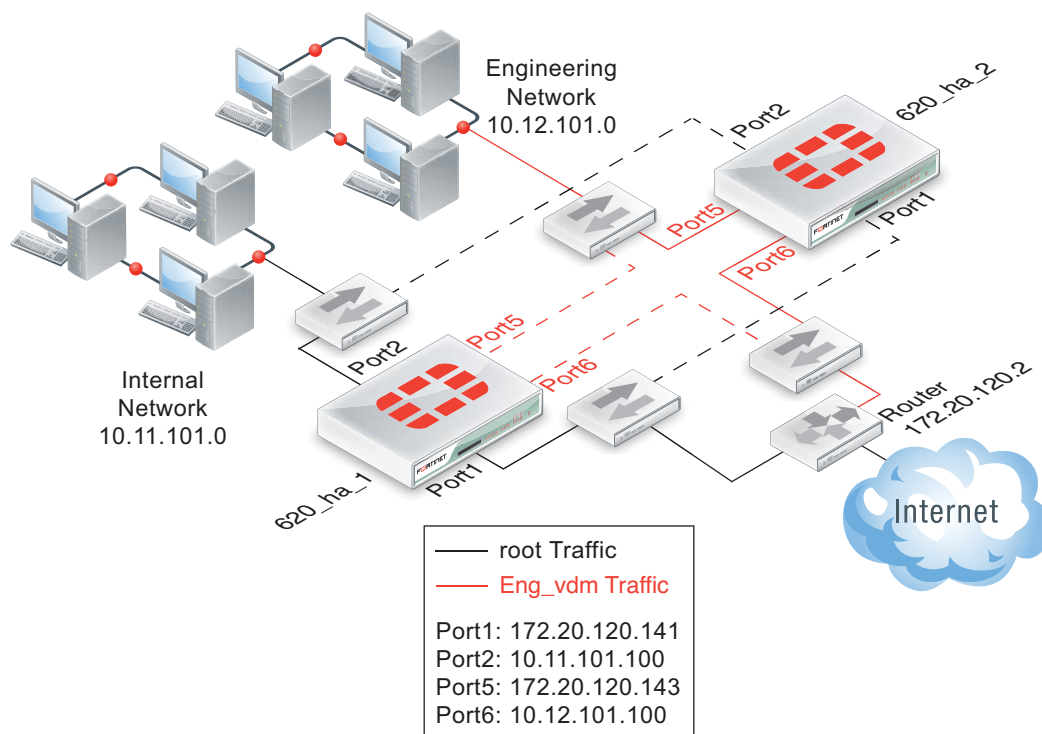

### Example virtual clustering network topology

[Figure 198](#) shows a typical FortiGate-620B HA virtual cluster consisting of two FortiGate-620B units (620\_ha\_1 and 620\_ha\_2) connected to an internal network, an engineering network and the Internet. To simplify the diagram the heartbeat connections are not shown.

The traffic from the internal network is processed by the root VDOM, which includes the port1 and port2 interfaces. The traffic from the engineering network is processed by the Eng\_vdm VDOM, which includes the port5 and port6 interfaces. VDOM partitioning is configured so that all traffic from the internal network is processed by 620\_ha\_1 and all traffic from the engineering network is processed by 620\_ha\_2.

This virtual cluster uses the default FortiGate-620B heartbeat interfaces (port3 and port4).

**Figure 198:**Example virtual cluster of two FortiGate-620B units showing VDOM partitioning

## General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

### General configuration steps

1. Configure the FortiGate units for HA operation.
  - Optionally change each unit's host name.
  - Configure HA.
2. Connect the cluster to the network.
3. Configure VDOM settings for the cluster:
  - Enable multiple VDOMs.
  - Add the Eng\_vdm VDOM.
  - Add port5 and port6 to the Eng\_vdm.
4. Configure VDOM partitioning.
5. Confirm that the cluster units are operating as a virtual cluster and add basic configuration settings to the cluster.
  - View cluster status from the web-based manager or CLI.
  - Add a password for the admin administrative account.
  - Change the IP addresses and netmasks of the port1, port2, port5, and port6 interfaces.
  - Add a default routes to each VDOM.

## Configuring virtual clustering with two VDOMs and VDOM partitioning - web-based manager

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

### To configure the FortiGate-620B units for HA operation

1. Power on the first FortiGate-620B unit and log into the web-based manager.
2. On the *System Information* dashboard widget, beside *Host Name* select *Change*.
3. Enter a new Host Name for this FortiGate unit.

<b>New Name</b>	620_ha_1
-----------------	----------

4. Select OK.
5. Go to *System > Config > HA* and change the following settings.

<b>Mode</b>	Active-Passive
-------------	----------------

<b>Group Name</b>	vexample2.com
-------------------	---------------

<b>Password</b>	vHA_pass_2
-----------------	------------

6. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC”](#))

[addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate unit.
8. Repeat these steps for the second FortiGate unit.  
Set the second FortiGate unit host name to:

---

<b>New Name</b>	620_ha_2
-----------------	----------

---

### To connect the cluster to the network

1. Connect the port1 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.
2. Connect the port5 interfaces of 620\_ha\_1 and 620\_ha\_2 to switch connected to the Internet. You could use the same switch for the port1 and port5 interfaces.
3. Connect the port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.
4. Connect the port6 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the engineering network.
5. Connect the port3 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
6. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
7. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete you can continue.

### To configure VDOM settings for the cluster

1. Log into the web-based manager.
2. On the *System Information* dashboard widget, beside *Virtual Domain* select *Enable*.
3. Select OK and then log back into the web-based manager.
4. Go to *System > VDOM* and select *Create New* to add a new VDOM.

<b>Name</b>	Eng_vdm
-------------	---------

5. Go to *System > Network > Interfaces*.
6. Edit the *port5* interface, add it to the Eng\_vdm VDOM and configure other interface settings:

<b>Alias</b>	Engineering_external
<b>Virtual Domain</b>	Eng_vdm
<b>IP/Netmask</b>	172.20.120.143/24

7. Select OK.
8. Edit the *port6* interface, add it to the Eng\_vdm VDOM and configure other interface settings:

<b>Alias</b>	Engineering_internal
<b>Virtual Domain</b>	Eng_vdm
<b>IP/Netmask</b>	10.120.101.100/24
<b>Administrative Access</b>	HTTPS, PING, SSH

9. Select OK.

### To add a default route to each VDOM

1. Go to *System > VDOM* and Enter the root VDOM.

2. Go to *Router > Static > Static Routes*.
3. Change the default route.

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Gateway</b>	172.20.120.2
<b>Device</b>	port1
<b>Distance</b>	10

4. Select *Global*.
5. Go to *System > VDOM* and Enter the Eng\_vdm VDOM.
6. Go to *Router > Static > Static Routes*.
7. Change the default route.

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Gateway</b>	172.20.120.2
<b>Device</b>	port5
<b>Distance</b>	10

#### To configure VDOM partitioning

1. Go to *System > Config > HA*.  
The cluster members shows two cluster units in Virtual Cluster 1.
2. Edit the cluster unit with the *Role of MASTER*.
3. Change *VDOM partitioning* to move the *Eng\_vdm* to the *Virtual Cluster 2* list.
4. Select OK.
5. Change the Virtual Cluster 1 and Virtual Cluster 2 device priorities for each cluster unit to the following:

<b>Host Name</b>	<b>Device Priority</b>	
	<b>Virtual Cluster 1</b>	<b>Virtual Cluster 2</b>
<b>620_ha_1</b>	200	100
<b>620_ha_2</b>	100	200

You can do this by editing the HA configurations of each cluster unit in the cluster members list and changing device priorities.

Since the device priority of Virtual Cluster 1 is highest for 620\_ha\_1 and since the root VDOM is in Virtual Cluster 1, all traffic for the root VDOM is processed by 620\_ha\_1.

Since the device priority of Virtual Cluster 2 is highest for 620\_ha\_2 and since the Eng\_vdm VDOM is in Virtual Cluster 2, all traffic for the Eng\_vdm VDOM is processed by 620\_ha\_2.

#### To view cluster status and verify the VDOM partitioning configuration

1. Log into the web-based manager.

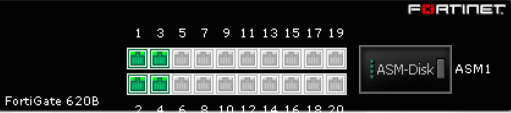

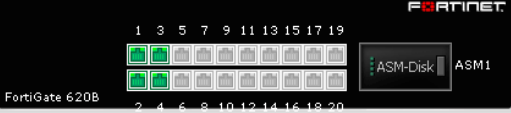

## 2. Go to *System > Config > HA*.

The cluster members list should show the following:

- Virtual Cluster 1 contains the root VDOM.
- 620\_ha\_1 is the primary unit (master) for Virtual Cluster 1.
- Virtual Cluster 2 contains the Eng\_vdm VDOM.
- 620\_ha\_2 is the primary unit (master) for Virtual Cluster 2.

**Figure 199:**Example virtual clustering cluster members list

Virtual Cluster 1		<a href="#">View HA Statistics</a>			
Virtual Domains: root		Cluster Member	Hostname	Role	Priority
		620_ha_1	MASTER	128	
		620_ha_2	SLAVE	128	
Virtual Cluster 2		Cluster Member	Hostname	Role	Priority
		620_ha_2	MASTER	128	
		620_ha_1	SLAVE	128	

## To test the VDOM partitioning configuration

You can do the following to confirm that traffic for the root VDOM is processed by 620\_ha\_1 and traffic for the Eng\_vdm is processed by 620\_ha\_2.

1. Log into the web-based manager by connecting to port2 using IP address 10.11.101.100.  
You will log into 610\_ha\_1 because port2 is in the root VDOM and all traffic for this VDOM is processed by 610\_ha\_1. You can confirm that you have logged into 610\_ha\_1 by checking the HTML title displayed by your web browser. The title will include the 610\_ha\_1 host name. Also on the System Information dashboard widget displays the serial number of the 610\_ha\_1 FortiGate unit.
2. Log into the web-based manager by connecting to port6 using IP address 10.12.101.100.  
You will log into 610\_ha\_2 because port6 is in the Eng\_vdm VDOM and all traffic for this VDOM is processed by 610\_ha\_2.
3. Add security policies to the root virtual domain that allows communication from the internal network to the Internet and connect to the Internet from the internal network.
4. Log into the web-based manager and go to *Config > System > HA* and select *View HA Statistics*.  
The statistics display shows more active sessions, total packets, network utilization, and total bytes for the 620\_ha\_1 unit.
5. Add security policies to the Eng\_vdm virtual domain that allow communication from the engineering network to the Internet and connect to the Internet from the engineering network.

6. Log into the web-based manager and go to *Config > System > HA* and select *View HA Statistics*.

The statistics display shows more active sessions, total packets, network utilization, and total bytes for the 620\_ha\_2 unit.

## Configuring virtual clustering with two VDOMs and VDOM partitioning - CLI

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

### To configure the FortiGate-620B units for HA operation

1. Power on the first FortiGate-620B unit and log into the CLI.
2. Change the host name for this FortiGate unit:

```
config system global
    set hostname 620_ha_1
end
```

3. Configure HA settings.

```
config system ha
    set mode a-p
    set group-name vexample2.com
    set password vHA_pass_2
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses”](#) on

[page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Display the HA configuration (optional).

```
get system ha
group-id          : 0
group-name        : vexample2.com
mode              : a-p
password          : *
hbdev             : "port3" 50 "port4" 50
session-sync-dev  :
route-ttl         : 10
route-wait        : 0
route-hold        : 10
sync-config       : enable
encryption        : disable
authentication    : disable
hb-interval       : 2
hb-lost-threshold : 20
helo-holddown     : 20
arps              : 5
arps-interval     : 8
session-pickup    : disable
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status    : disable
ha-eth-type       : 8890
hc-eth-type       : 8891
l2ep-eth-type     : 8893
subsecond         : disable
vcluster2         : disable
vcluster-id       : 1
override          : disable
priority          : 128
monitor           :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom              : "root"
```

5. Power off the first FortiGate unit.

6. Repeat these steps for the second FortiGate unit.

Set the other FortiGate unit host name to:

```
config system global
    set hostname 620_ha_2
end
```

**To connect the cluster to the network**

1. Connect the port1 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the Internet.
2. Connect the port5 interfaces of 620\_ha\_1 and 620\_ha\_2 to switch connected to the Internet.  
You could use the same switch for port1 and port5.

3. Connect the port2 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the internal network.
4. Connect the port6 interfaces of 620\_ha\_1 and 620\_ha\_2 to a switch connected to the engineering network.
5. Connect the port3 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
6. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
7. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete you can continue.

### **To configure VDOM settings for the cluster**

1. Log into the CLI.
2. Enter the following command to enable multiple VDOMs for the cluster.

```
config system global
    set vdom-admin enable
end
```
3. Log back into the CLI.
4. Enter the following command to add the Eng\_vdm VDOM:

```
config vdom
    edit Eng_vdm
end
```
5. Edit the port5 interface, add it to the Eng\_vdm VDOM and configure other interface settings:

```
config global
    config system interface
        edit port5
            set vdom Eng_vdm
            set alias Engineering_external
            set ip 172.20.12.143/24
        next
        edit port6
            set vdom Eng_vdm
            set alias Engineering_internal
            set ip 10.120.101.100/24
        end
    end
end
```

### To add a default route to each VDOM

1. Enter the following command to add default routes to the root and Eng\_vdm VDOMs.

```
config vdom
  edit root
    config router static
      edit 1
        set dst 0.0.0.0/0.0.0.0
        set gateway 172.20.120.2
        set device port1
      end
    next
  edit Eng_vdm
    config router static
      edit 1
        set dst 0.0.0.0/0.0.0.0
        set gateway 172.20.120.2
        set device port5
      end
    end
end
```

### To configure VDOM partitioning

1. Enter the get system ha status command to view cluster unit status:

For example, from the 620\_ha\_2 cluster unit CLI:

```
config global
  get system ha status
  Model: 620
  Mode: a-p
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2          FG600B3908600825 0
  Slave :128 620_ha_1          FG600B3908600705 1
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

This command output shows that VDOM partitioning has not been configured because only virtual cluster 1 is shown. The command output also shows that the 620\_ha\_2 is the primary unit for the cluster and for virtual cluster 1 because this cluster unit has the highest serial number

2. Enter the following commands to configure VDOM partitioning:

```
config global
  config system ha
    set vcluster2 enable
    config secondary-vcluster
      set vdom Eng_vdm
    end
  end
end
```

3. Enter the `get system ha status` command to view cluster unit status:

For example, from the 620\_ha\_2 cluster unit CLI:

```
config global
  get system ha status
  Model: 620
  Mode: a-p
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2          FG600B3908600825 0
  Slave :128 620_ha_1          FG600B3908600705 1
  number of vcluster: 2
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
  vcluster 2: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

This command output shows VDOM partitioning has been configured because both virtual cluster 1 and virtual cluster 2 are visible. However the configuration is not complete because 620\_ha\_2 is the primary unit for both virtual clusters. The command output shows this because under both vcluster entries the `Master` entry shows FG600B3908600825, which is the serial number of 620\_ha\_2. As a result of this configuration, 620\_ha\_2 processes traffic for both VDOMs and 620\_ha\_1 does not process any traffic.

4. Change the Virtual Cluster 1 and Virtual Cluster 2 device priorities for each cluster unit so that 620\_ha\_1 processes virtual cluster 1 traffic and 620\_ha\_2 processes virtual cluster 2 traffic.

Since the root VDOM is in virtual cluster 1 and the Eng\_vdm VDOM is in virtual cluster 2 the result of this configuration will be that 620\_ha\_1 will process all root VDOM traffic and

620\_ha\_2 will process all Eng\_vdm traffic. You make this happen by changing the cluster unit device priorities for each virtual cluster. You could use the following settings:

Device Priority		
Host Name	Virtual Cluster 1	Virtual Cluster 2
620_ha_1	200	100
620_ha_2	100	200

Since the device priority is not synchronized you can edit the device priorities of each virtual cluster on each FortiGate unit separately. To do this:

- Log into the CLI and note the FortiGate unit you have actually logged into (for example, by checking the host name displayed in the CLI prompt).
- Change the virtual cluster 1 and 2 device priorities for this cluster unit.
- Then use the `execute ha manage` command to log into the other cluster unit CLI and set its virtual cluster 1 and 2 device priorities.

Enter the following commands from the 620\_ha\_1 cluster unit CLI:

```
config global
  config system ha
    set priority 200
    config secondary-vcluster
      set priority 100
    end
  end
end
```

Enter the following commands from the 620\_ha\_2 cluster unit CLI:

```
config global
  config system ha
    set priority 100
    config secondary-vcluster
      set priority 200
    end
  end
end
```

The cluster may renegotiate during this step resulting in a temporary loss of connection to the CLI and a temporary service interruption.

Since the device priority of Virtual Cluster 1 is highest for 620\_ha\_1 and since the root VDOM is in Virtual Cluster 1, all traffic for the root VDOM is processed by 620\_ha\_1.

Since the device priority of Virtual Cluster 2 is highest for 620\_ha\_2 and since the Eng\_vdm VDOM is in Virtual Cluster 2, all traffic for the Eng\_vdm VDOM is processed by 620\_ha\_2.

### To verify the VDOM partitioning configuration

1. Log into the 620\_ha\_2 cluster unit CLI and enter the following command:

```
config global
get system ha status
Model: 620
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Slave :100 620_ha_2          FG600B3908600825 0
Master:200 620_ha_1          FG600B3908600705 1
number of vcluster: 2
vcluster 1: standby 169.254.0.2
Slave :1 FG600B3908600825
Master:0 FG600B3908600705
vcluster 2: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

The command output shows that 620\_ha\_1 is the primary unit for virtual cluster 1 (because the command output show the Master of virtual cluster 1 is the serial number of 620\_ha\_1) and that 620\_ha\_2 is the primary unit for virtual cluster 2.

If you enter the same command from the 620\_ha\_1 CLI the same information is displayed but in a different order. The command always displays the status of the cluster unit that you are logged into first.

```
config global
get system ha status
Model: 620
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:200 620_ha_1          FG600B3908600705 1
Slave :100 620_ha_2          FG600B3908600825 0
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master:0 FG600B3908600705
Slave :1 FG600B3908600825
vcluster 2: standby 169.254.0.1
Slave :1 FG600B3908600705
Master:0 FG600B3908600825
```

### To test the VDOM partitioning configuration

You can do the following to confirm that traffic for the root VDOM is processed by 620\_ha\_1 and traffic for the Eng\_vdm is processed by 620\_ha\_2. These steps assume the cluster is operating correctly.

1. Log into the CLI by connecting to port2 using IP address 10.11.101.100.

You will log into 610\_ha\_1 because port2 is in the root VDOM and all traffic for this VDOM is processed by 610\_ha\_1. You can confirm that you have logged into 610\_ha\_1 by checking

the host name in the CLI prompt. Also the `get system status` command displays the status of the 610\_ha\_1 cluster unit.

2. Log into the web-based manager or CLI by connecting to port6 using IP address 10.12.101.100.

You will log into 610\_ha\_2 because port6 is in the Eng\_vdm VDOM and all traffic for this VDOM is processed by 610\_ha\_2.

3. Add security policies to the root virtual domain that allow communication from the internal network to the Internet and connect to the Internet from the internal network.
4. Log into the web-based manager and go to *Config > System > HA* and select *View HA Statistics*.

The statistics display shows more active sessions, total packets, network utilization, and total bytes for the 620\_ha\_1 unit.

5. Add security policies to the Eng\_vdm virtual domain that allow communication from the engineering network to the Internet and connect to the Internet from the engineering network.
6. Log into the web-based manager and go to *Config > System > HA* and select *View HA Statistics*.

The statistics display shows more active sessions, total packets, network utilization, and total bytes for the 620\_ha\_2 unit.

## Example: inter-VDOM links in a virtual clustering configuration

In a virtual domain configuration you can use inter-VDOM links to route traffic between two virtual domains operating in a single FortiGate unit without using physical interfaces. Adding an inter-VDOM link has the affect of adding two interfaces to the FortiGate unit and routing traffic between the virtual domains using the inter-VDOM link interfaces.

In a virtual clustering configuration inter-VDOM links can only be made between virtual domains that are in the same virtual cluster. So, if you are planning on configuring inter-VDOM links in a virtual clustering configuration, you should make sure the virtual domains that you want to link are in the same virtual cluster.

For example, the following tables show an example virtual clustering configuration where each virtual cluster contains three virtual domains. In this configuration you can configure inter-VDOM links between root and vdom\_1 and between vdom\_2 and vdom\_3. But, you cannot configure inter-VDOM links between root and vdom\_2 or between vdom\_1 and vdom\_3 (and so on).

Virtual Domains	Hostname	
	FortiGate_A	FortiGate_B
root	Priority	Priority
vdom_1	200	100
Role		Role
Primary		Subordinate

Virtual Domains	Hostname	
	FortiGate_A	FortiGate_B
vdom_2	<b>Priority</b>	<b>Priority</b>
vdom_3	100	200
	<b>Role</b>	<b>Role</b>
	Subordinate	Primary

## Configuring inter-VDOM links in a virtual clustering configuration

Configuring inter-VDOM links in a virtual clustering configuration is very similar to configuring inter-VDOM links for a standalone FortiGate unit. The main difference the `config system vdom-link` command includes the `vcluster` keyword. The default setting for `vcluster` is `vcluster1`. So you only have to use the `vcluster` keyword if you are added an inter-VDOM link to virtual cluster 2.

### To add an inter-VDOM link to virtual cluster 1

This procedure describes how to create an inter-VDOM link to virtual cluster 1 that results in a link between the root and vdom\_1 virtual domains.

Inter-VDOM links are also called internal point-to-point interfaces.

- 1 Add an inter-VDOM link called `vc1link`.

```
config global
    config system vdom-link
        edit vc1link
    end
```

Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc1link0` and `vc1link1`. These interfaces appear in all CLI and web-based manager interface lists. These interfaces can only be added to virtual domains in virtual cluster 1.

2. Bind the `vc1link0` interface to the root virtual domain and bind the `vc1link1` interface to the `vdom_1` virtual domain.

```
config system interface
    edit vc1link0
        set vdom root
    next
    edit vc1link1
        set vdom vdom_1
    end
```

### To add an inter-VDOM link to virtual cluster 2

This procedure describes how to create an inter-VDOM link to virtual cluster 2 that results in a link between the `vdom_2` and `vdom_3` virtual domains.

- 1 Add an inter-VDOM link called `vc2link`.

```
config global
    config system vdom-link
        edit vc2link
            set vcluster vcluster2
        end
```

Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc2link0` and `vc2link1`. These interfaces appear in all CLI and web-based manager interface lists. These interfaces can only be added to virtual domains in virtual cluster 2.

2. Bind the `vc2link0` interface to the `vdom_2` virtual domain and bind the `vc2link1` interface to the `vdom_3` virtual domain.

```
config system interface
    edit vc2link0
        set vdom vdom_2
    next
    edit vc2link1
        set vdom vdom_3
    end
```

## Troubleshooting virtual clustering

Troubleshooting virtual clusters is similar to troubleshooting any cluster (see [“Troubleshooting HA clusters” on page 1212](#)). This section describes a few testing and troubleshooting techniques for virtual clustering.

### To test the VDOM partitioning configuration

You can do the following to confirm that traffic for different VDOMs will be distributed among both FortiGate units in the virtual cluster. These steps assume the cluster is otherwise operating correctly.

1. Log into the web-based manager or CLI using the IP addresses of interfaces in each VDOM.  
Confirm that you have logged into the FortiGate unit that should be processing traffic for that VDOM by checking the HTML title displayed by your web browser or the CLI prompt. Both of these should include the host name of the cluster unit that you have logged into. Also on the system Dashboard, the System Information widget displays the serial number of the FortiGate unit that you logged into. From the CLI the `get system status` command displays the status of the cluster unit that you logged into.
2. To verify that the correct cluster unit is processing traffic for a VDOM:
  - Add security policies to the VDOM that allow communication between the interfaces in the VDOM.
  - Optionally enable traffic logging and other monitoring for that VDOM and these security policies.
  - Start communication sessions that pass traffic through the VDOM.
  - Log into the web-based manager and go to *Config > System > HA* and select *View HA Statistics*. Verify that the statistics display shows more active sessions, total packets, network utilization, and total bytes for the unit that should be processing all traffic for the VDOM.
  - Optionally check traffic logging and the Top Sessions Widget for the FortiGate unit that should be processing traffic for that VDOM to verify that the traffic is being processed by this FortiGate unit.

# Full mesh HA

This chapter provides an introduction to full mesh HA and also contains general procedures and configuration examples that describe how to configure FortiGate full mesh HA.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

This chapter contains the following sections:

- [Full mesh HA overview](#)
- [Example: full mesh HA configuration](#)
- [Troubleshooting full mesh HA](#)

## Full mesh HA overview

When two or more FortiGate units are connected to a network in an HA cluster the reliability of the network is improved because the HA cluster replaces a single FortiGate unit as a single point of failure. With a cluster, a single FortiGate unit is replaced by a cluster of two or more FortiGate units.

However, even with a cluster, potential single points of failure remain. The interfaces of each cluster unit connect to a single switch and that switch provides a single connection to the network. If the switch fails or if the connection between the switch and the network fails service is interrupted to that network.

The HA cluster does improve the reliability of the network because switches are not as complex components as FortiGate units, so are less likely to fail. However, for even greater reliability, a configuration is required that includes redundant connections between the cluster the networks that it is connected to.

FortiGate models that support 802.3ad Aggregate or Redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster.

This redundant configuration can be achieved using FortiGate 802.3ad Aggregate or Redundant interfaces and a full mesh HA configuration. In a full mesh HA configuration, you connect an HA cluster consisting of two or more FortiGate units to the network using 802.3ad Aggregate or Redundant interfaces and redundant switches. Each 802.3ad Aggregate or Redundant interface is connected to two switches and both of these switches are connected to the network.

The resulting full mesh configuration, an example is shown in [Figure 200](#), includes redundant connections between all network components. If any single component or any single connection fails, traffic automatically switches to the redundant component and connection and traffic flow resumes.

**Figure 200:**Single points of failure in a standalone and HA network configuration

### Full mesh HA and redundant heartbeat interfaces

A full mesh HA configuration also includes redundant HA heartbeat interfaces. At least two heartbeat interfaces should be selected in the HA configuration and both sets of HA heartbeat interfaces should be connected. The HA heartbeat interfaces do not have to be configured as redundant interfaces because the FGCP handles failover between heartbeat interfaces.

### Full mesh HA, redundant interfaces and 802.3ad aggregate interfaces

Full mesh HA is supported for both redundant interfaces and 802.3ad aggregate interfaces. In most cases you would simply use redundant interfaces. However, if your switches support 802.3ad aggregate interfaces and split multi-trunking you can use aggregate interfaces in place of redundant interfaces for full mesh HA. One advantage of using aggregate interfaces is that all

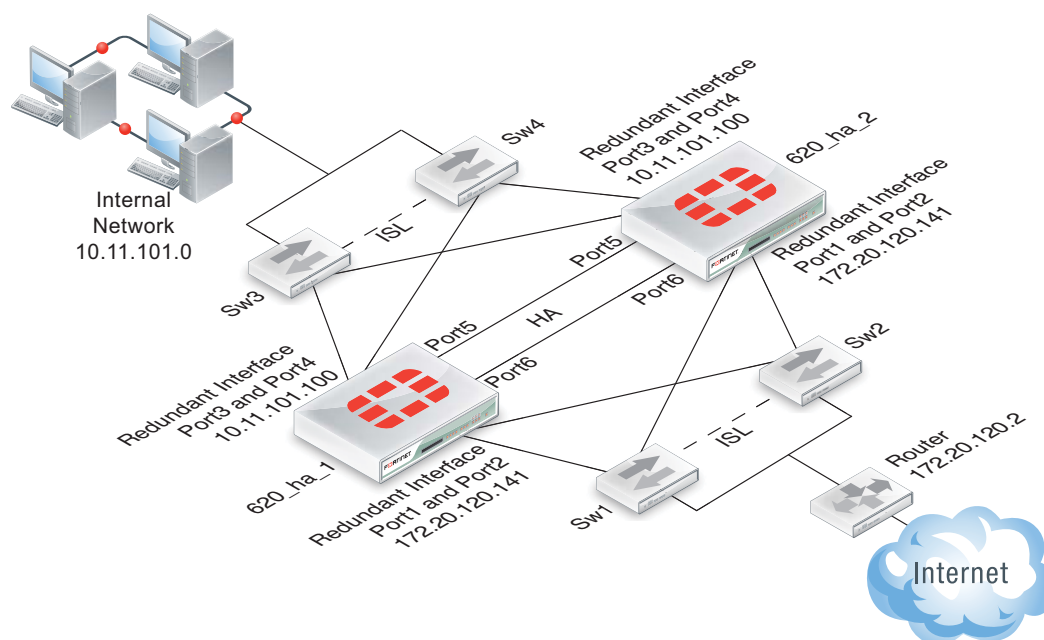

of the physical interfaces in the aggregate interface can send and receive packets. As a result, using aggregate interfaces may increase the bandwidth capacity of the cluster.

Usually redundant and aggregate interfaces consist of two physical interfaces. However, you can add more than two physical interfaces to a redundant or aggregate interface. Adding more interfaces can increase redundancy protection. Adding more interfaces can also increase bandwidth capacity if you are using 802.3ad aggregate interfaces.

## Example: full mesh HA configuration

Figure 200 shows a full mesh HA configuration with a cluster of two FortiGate-620b units. This section describes the FortiGate configuration settings and network components required for a full mesh HA configuration. This section also contains example steps for setting up this full mesh HA configuration. The procedures in this section describe one of many possible sequences of steps for configuring full mesh HA. As you become more experienced with FortiOS, HA, and full mesh HA you may choose to use a different sequence of configuration steps.

**Figure 201:** Full Mesh HA configuration

For simplicity these procedures assume that you are starting with two new FortiGate units set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

These procedures describe how to configure a cluster operating in NAT/Route mode because NAT/Route is the default FortiGate operating mode. However, the steps are the same if the cluster operates in Transparent mode. You can either switch the cluster units to operate in Transparent mode before beginning these procedures, or you can switch the cluster to operate in Transparent mode after HA is configured and the cluster is connected and operating.

## FortiGate-620B full mesh HA configuration

The two FortiGate-620B units (620\_ha\_1 and 620\_ha\_2) can be operating in NAT/Route or Transparent mode. Aside from the standard HA settings, the FortiGate-620B configuration includes the following:

- The port5 and port6 interfaces configured as heartbeat interfaces. A full mesh HA configuration also includes redundant HA heartbeat interfaces.
- The port1 and port2 interfaces added to a redundant interface. Port1 is the active physical interface in this redundant interface. To make the port1 interface the active physical interface it should appear above the port2 interface in the redundant interface configuration.
- The port3 and port4 interfaces added to a redundant interface. Port3 is the active physical interface in this redundant interface. To make the port3 interface the active physical interface it should appear above the port4 interface in the redundant interface configuration.

## Full mesh switch configuration

The following redundant switch configuration is required:

- Two redundant switches (Sw3 and Sw4) connected to the internal network. Establish an interswitch-link (ISL) between them.
- Two redundant switches (Sw1 and Sw2) connected to the Internet. Establish an interswitch-link (ISL) between them.

## Full mesh network connections

Make the following physical network connections for 620\_ha\_1:

- Port1 to Sw1 (active)
- Port2 to Sw2 (inactive)
- Port3 to Sw3 (active)
- Port4 to Sw4 (inactive)

Make the following physical network connections for 620\_ha\_2:

- Port1 to Sw2 (active)
- Port2 to Sw1 (inactive)
- Port3 to Sw4 (active)
- Port4 to Sw3 (inactive)

## How packets travel from the internal network through the full mesh cluster and to the Internet

If the cluster is operating in active-passive mode and 620\_ha\_2 is the primary unit, all packets take the following path from the internal network to the internet:

1. From the internal network to Sw4. Sw4 is the active connection to 620\_ha\_2; which is the primary unit. The primary unit receives all packets.
2. From Sw4 to the 620\_ha\_2 port3 interface. Active connection between Sw4 and 620\_ha\_2. Port3 is the active member of the redundant interface.
3. From 620\_ha\_2 port3 to 620\_ha\_2 port1. Active connection between 620\_ha\_2 and Sw2. Port1 is the active member of the redundant interface.
4. From Sw2 to the external router and the Internet.

## Configuring FortiGate-620B units for HA operation - web-based manager

Each FortiGate-620B unit in the cluster must have the same HA configuration.

### To configure the FortiGate-620B units for HA operation

1. Connect to the web-based manager of one of the FortiGate-620B units.
2. On the *System Information* dashboard widget, beside *Host Name* select *Change*.
3. Enter a new Host Name for this FortiGate unit.

<b>New Name</b>	620_ha_1
-----------------	----------

4. Go to *System > Config > HA* and change the following settings.

<b>Mode</b>	Active-Active
-------------	---------------

<b>Group Name</b>	Rexample1.com
-------------------	---------------

<b>Password</b>	RHA_pass_1
-----------------	------------

#### Heartbeat Interface

	<b>Enable</b>	<b>Priority</b>
<b>port5</b>	Select	50
<b>port6</b>	Select	50

5. Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10

- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

6. Power off the first FortiGate unit.
7. Repeat these steps for the second FortiGate unit.  
Set the second FortiGate unit host name to:

---

<b>New Name</b>	620_ha_2
-----------------	----------

---

### To connect the cluster to your network

1. Make the following physical network connections for 620\_ha\_1:
  - Port1 to Sw1 (active)
  - Port2 to Sw2 (inactive)
  - Port3 to Sw3 (active)
  - Port4 to Sw4 (inactive)
2. Make the following physical network connections for 620\_ha\_2:
  - Port1 to Sw2 (active)
  - Port2 to Sw1 (inactive)
  - Port3 to Sw4 (active)
  - Port4 to Sw3 (inactive)
3. Connect Sw3 and Sw4 to the internal network.
4. Connect Sw1 and Sw2 to the external router.
5. Enable ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.
6. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete the cluster is ready to be configured for your network.

## To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

The System Information dashboard widget shows the *Cluster Name* (Rexample1.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

2. Go to *System > Config > HA* to view the cluster members list.

The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

## To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

## To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster web-based manager.
2. Go to *System > Admin > Administrators*.
3. For *admin*, select the *Change Password* icon
4. Enter and confirm a new password.
5. Select OK.
6. Go to *Router > Static > Static Routes* and temporarily delete the default route.  
You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.
7. Go to *System > Network > Interfaces* and select *Create New* and configure the redundant interface to connect to the Internet.

<b>Name</b>	Port1_Port2
<b>Type</b>	Redundant
<b>Physical Interface Members</b>	
<b>Selected Interfaces</b>	port1, port2
<b>IP/Netmask</b>	172.20.120.141/24

8. Select OK.
9. Select *Create New* and configure the redundant interface to connect to the internal network.

<b>Name</b>	Port3_Port4
<b>Type</b>	Redundant
<b>Physical Interface Members</b>	
<b>Selected Interfaces</b>	port3, port4

<b>IP/Netmask</b>	10.11.101.100/24
<b>Administrative Access</b>	HTTPS, PING, SSH

**10.**Select OK.

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Notice that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

**11.**Go to *Router > Static > Static Routes*.

**12.**Add the default route.

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Gateway</b>	172.20.120.2
<b>Device</b>	Port1_Port2
<b>Distance</b>	10

**13.**Select OK.

**To configure HA port monitoring for the redundant interfaces**

1. Go to *System > Config > HA*.
2. In the cluster members list, edit the primary unit.

3. Configure the following port monitoring for the redundant interfaces:

Port Monitor	
Port1_Port2	Select
Port3_Port4	Select

4. Select OK.

## Configuring FortiGate-620B units for HA operation - CLI

Each FortiGate-620B unit in the cluster must have the same HA configuration. Use the following procedure to configure the FortiGate-620B units for HA operation.

### To configure the FortiGate-620B units for HA operation

1. Connect to the CLI of one of the FortiGate-620B units.
2. Enter a new Host Name for this FortiGate unit.

```
config system global
    set hostname 620_ha_1
end
```

3. Configure HA settings.

```
config system ha
    set mode a-a
    set group-name Rexample1.com
    set password RHA_pass_1
    set hbdev port5 50 port6 50
end
```

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see [“Cluster virtual MAC addresses” on page 1300](#)). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-0b
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0e

- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Power off the first FortiGate unit.
5. Repeat these steps for the second FortiGate unit.

Set the other FortiGate unit host name to:

```
config system global
    set hostname 620_ha_2
end
```

### To connect the cluster to your network

1. Make the following physical network connections for 620\_ha\_1:
  - Port1 to Sw1 (active)
  - Port2 to Sw2 (inactive)
  - Port3 to Sw3 (active)
  - Port4 to Sw4 (inactive)
2. Make the following physical network connections for 620\_ha\_2:
  - Port1 to Sw2 (active)
  - Port2 to Sw1 (inactive)
  - Port3 to Sw4 (active)
  - Port4 to Sw3 (inactive)
3. Connect Sw3 and Sw4 to the internal network.
4. Connect Sw1 and Sw2 to the external router.
5. Enable ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.
6. Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete the cluster is ready to be configured for your network.

## To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into.  
If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit.  
If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit.  
If the command output includes `Current HA mode: standalone` the cluster unit is not operating in HA mode.
3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 620
  Mode: a-a
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2          FG600B3908600825 0
  Slave :128 620_ha_1          FG600B3908600705 1
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

4. Use the `execute ha manage` command to connect to the other cluster unit's CLI and use these commands to verify cluster status.

## To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGate units are not functioning as a cluster. See [“Troubleshooting HA clusters” on page 1212](#) to troubleshoot the cluster.

## To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings. Some steps use the CLI and some the web-based manager.

1. Log into the cluster CLI.
2. Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <password_str>
  end
```

3. Temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.

```
config router static
    delete 1
end
```

4. Go to *System > Network > Interface* and select *Create New* to add the redundant interface to connect to the Internet.

5. Add the redundant interface to connect to the Internet.

```
config sysetem interface
    edit Port1_Port2
        set type redundant
        set member port1 port2
    end
```

6. Add the redundant interface to connect to the internal network.

```
config sysetem interface
    edit Port3_Port4
        set type redundant
        set member port3 port4
    end
```

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: 00-09-0f-09-00-00
- port10 interface virtual MAC: 00-09-0f-09-00-01
- port11 interface virtual MAC: 00-09-0f-09-00-02
- port12 interface virtual MAC: 00-09-0f-09-00-03
- port13 interface virtual MAC: 00-09-0f-09-00-04
- port14 interface virtual MAC: 00-09-0f-09-00-05
- port15 interface virtual MAC: 00-09-0f-09-00-06
- port16 interface virtual MAC: 00-09-0f-09-00-07
- port17 interface virtual MAC: 00-09-0f-09-00-08
- port18 interface virtual MAC: 00-09-0f-09-00-09
- port19 interface virtual MAC: 00-09-0f-09-00-0a
- port2 interface virtual MAC: 00-09-0f-09-00-00 (same as port1)
- port20 interface virtual MAC: 00-09-0f-09-00-0c
- port3 interface virtual MAC: 00-09-0f-09-00-0d
- port4 interface virtual MAC: 00-09-0f-09-00-0d (same as port3)
- port5 interface virtual MAC: 00-09-0f-09-00-0f
- port6 interface virtual MAC: 00-09-0f-09-00-10
- port7 interface virtual MAC: 00-09-0f-09-00-11
- port8 interface virtual MAC: 00-09-0f-09-00-12
- port9 interface virtual MAC: 00-09-0f-09-00-13

7. Go to *Router > Static*.

**8. Add the default route.**

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device Port1_Port2
  end
```

**To configure HA port monitoring for the redundant interfaces**

**1. Enter the following command to configure port monitoring for the redundant interfaces:**

```
config system ha
  set monitor Port1_Port2 Port3_Port4
end
```

## Troubleshooting full mesh HA

Troubleshooting full mesh HA clusters is similar to troubleshooting any cluster (see [“Troubleshooting HA clusters” on page 1212](#) or [“Troubleshooting virtual clustering” on page 1238](#)). The configuration and operation of a full mesh HA cluster is very similar to the configuration and operation of a standard cluster. The only differences relate to the configuration, connection, and operation of the redundant interfaces and redundant switches.

- Make sure the redundant interfaces and switches are connected correctly. With so many connections it is possible to make mistakes or for cables to become disconnected.
- Confirm that the configuration of the cluster unit 802.3ad Aggregate or Redundant interfaces is correct according to the configuration procedures in this chapter.
- In some configurations with some switch hardware, MAC-learning delays on the inter-switch links on the surrounding topologies may occur. The delays occur if the gratuitous ARP packets sent by the cluster after a failover are delayed by the switches before being sent across the inter-switch link. If this happens the surrounding topologies may be delayed in recognizing the failover and will keep sending packets to the MAC address of the failed primary unit resulting in lost traffic. Resolving this problem may require changing the configuration of the switch or replacing them with switch hardware that does not delay the gratuitous ARP packets.

# Operating a cluster

With some exceptions, you can operate a cluster in much the same way as you operate a standalone FortiGate unit. This chapter describes those exceptions and also the similarities involved in operating a cluster instead of a standalone FortiGate unit.

This chapter contains the following sections:

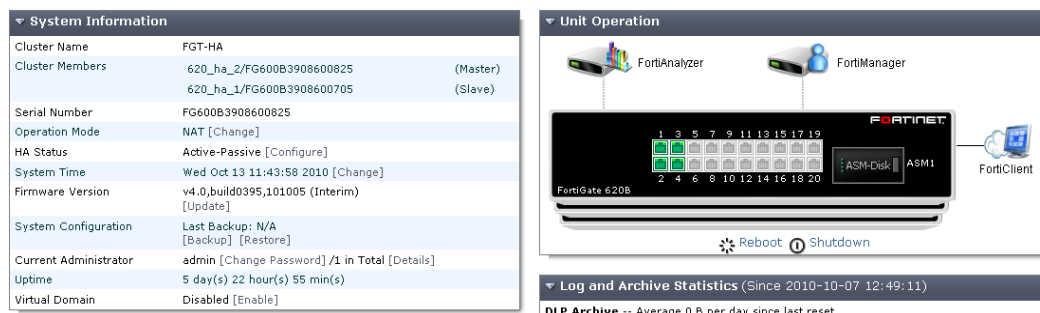

- [Operating a cluster](#)
- [Operating a virtual cluster](#)
- [Managing individual cluster units using a reserved management interface](#)
- [The primary unit acts as a router for subordinate unit management traffic](#)

## Operating a cluster

The configurations of all of the FortiGate units in a cluster are synchronized so that the cluster units can simulate a single FortiGate unit. Because of this synchronization, you manage the HA cluster instead of managing the individual cluster units. You manage the cluster by connecting to the web-based manager using any cluster interface configured for HTTPS or HTTP administrative access. You can also manage the cluster by connecting to the CLI using any cluster interface configured for SSH or telnet administrative access.

The cluster web-based manager dashboard displays the cluster name, the host name and serial number of each cluster member, and also shows the role of each unit in the cluster. The roles can be master (primary unit) and slave (subordinate units). The dashboard also displays a cluster unit front panel illustration.

**Figure 202:**Example cluster web-based manager dashboard

You can also go to *System > Config > HA* to view the cluster members list. This includes status information for each cluster unit. You can also use the cluster members list for a number of cluster management functions including changing the HA configuration of an operating cluster, changing the host name and device priority of a subordinate unit, and disconnecting a cluster unit from a cluster. See [“Cluster members list” on page 1268](#).

You can use log messages to view information about the status of the cluster. See [“Viewing and managing log messages for individual cluster units” on page 1261](#). You can use SNMP to manage the cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration information and receive traps.

You can configure a reserved management interface to manage individual cluster units. You can use this interface to access the web-based manager or CLI and to configure SNMP management for individual cluster units. See [“Managing individual cluster units using a reserved management interface” on page 1254](#).

You can manage individual cluster units by using SSH, telnet, or the CLI console on the web-based manager dashboard to connect to the CLI of the cluster. From the CLI you can use the `execute ha manage` command to connect to the CLI of any unit in the cluster.

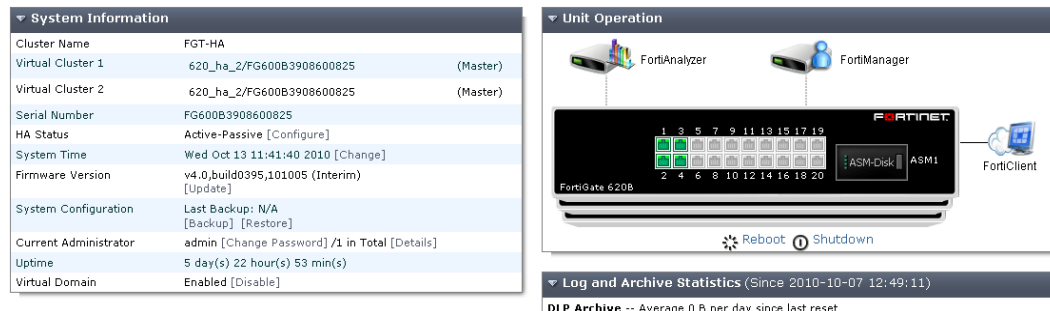

You can also manage individual cluster units by using a null-modem cable to connect to any cluster unit CLI. From there you can use the `execute ha manage` command to connect to the CLI of each unit in the cluster.

## Operating a virtual cluster

Managing a virtual cluster is very similar to managing a cluster that does not contain multiple virtual domains. Most of the information in this chapter applies to managing both kinds of clusters. This section describes what is different when managing a virtual cluster.

If virtual domains are enabled, the cluster web-based manager dashboard displays the cluster name and the role of each cluster unit in virtual cluster 1 and virtual cluster 2.

**Figure 203:**Example virtual clustering web-based manager dashboard

The configuration and maintenance options that you have when you connect to a virtual cluster web-based manager or CLI depend on the virtual domain that you connect to and the administrator account that you use to connect.

If you connect to a cluster as the administrator of a virtual domain, you connect directly to the virtual domain. Since HA virtual clustering is a global configuration, virtual domain administrators cannot see HA configuration options. However, virtual domain administrators see the host name of the cluster unit that they are connecting to on the web browser title bar or CLI prompt. This host name is the host name of the primary unit for the virtual domain. Also, when viewing log messages by going to *Log & Report > Log Access* virtual domain administrator can select to view log messages for either of the cluster units.

If you connect to a virtual cluster as the admin administrator you connect to the global web-based manager or CLI. Even so, you are connecting to an interface and to the virtual domain that the interface has been added to. The virtual domain that you connect to does not make a difference for most configuration and maintenance operations. However, there are a few exceptions. You connect to the FortiGate unit that functions as the primary unit for the virtual domain. So the host name displayed on the web browser title bar and on the CLI is the host name of this primary unit.

## Managing individual cluster units using a reserved management interface

You can provide direct management access to all cluster units by reserving a management interface as part of the HA configuration. Once this management interface is reserved, you can configure a different IP address, administrative access and other interface settings for this interface for each cluster unit. Then by connecting this interface of each cluster unit to your network you can manage each cluster unit separately from a different IP address. Configuration changes to the reserved management interface are not synchronized to other cluster units.

The reserved management interface provides direct management access to each cluster unit and gives each cluster unit a different identity on your network. This simplifies using external services, such as SNMP, to separately monitor and manage each cluster unit.

The reserved management interface is not assigned an HA virtual MAC address like other cluster interfaces. Instead the reserved management interface retains the permanent hardware address of the physical interface unless you change it using the `config system interface` command.

The reserved management interface and IP address should not be used for managing a cluster using FortiManager. To correctly manage a FortiGate HA cluster with FortiManager use the IP address of one of the cluster unit interfaces.

If you enable SNMP administrative access for the reserved management interface you can use SNMP to monitor each cluster unit using the reserved management interface IP address. To monitor each cluster unit using SNMP, just add the IP address of each cluster unit's reserved management interface to the SNMP server configuration. You must also enable direct management of cluster members in the cluster SNMP configuration.

If you enable HTTPS or HTTP administrative access for the reserved management interfaces you can connect to the web-based manager of each cluster unit. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. From the subordinate units the web-based manager has the same features as the primary unit except that unit-specific information is displayed for the subordinate unit, for example:

- The *Dashboard System Information* widget displays the subordinate unit serial number but also displays the same information about the cluster as the primary unit
- On the Cluster members list (go to *System > Config > HA*) you can change the HA configuration of the subordinate unit that you are logged into. For the primary unit and other subordinate units you can change only the host name and device priority.
- Log Access displays the logs of the subordinate that you are logged into first. You use the HA Cluster list to view the log messages of other cluster units including the primary unit.

If you enable SSH or TELNET administrative access for the reserved management interfaces you can connect to the CLI of each cluster unit. The CLI prompt contains the host name of the cluster unit that you have connected to. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. You can also use the `execute ha manage` command to connect to other cluster unit CLIs.

The reserved management interface is available in NAT/Route and in Transparent mode. It is also available if the cluster is operating with multiple VDOMs. In Transparent mode you cannot normally add an IP address to an interface. However, you can add an IP address to the reserved management interface.

## Configuring the reserved management interface and SNMP remote management of individual cluster units

This example describes how to configure SNMP remote management of individual cluster units using the HA reserved management interface. The configuration consists of two FortiGate-620B units already operating as a cluster. In the example, the port8 interface of each cluster unit is connected to the internal network using the switch and configured as the reserved management interface.

**Figure 204:**SNMP remote management of individual cluster units

**To configure the reserved management interface - web-based manager**

1. Go to *System > Config > HA*.
2. Edit the primary unit.
3. Select *Reserve Management Port for Cluster Member* and select port8.
4. Select OK.

**To configure the reserved management interface - CLI**

From the CLI you can also configure a default route that is only used by the reserved management interface.

1. Log into the CLI of any cluster unit.
2. Enter the following command to enable the reserved management interface, set port8 as the reserved interface, and add a default route of 10.11.101.100 for the reserved management interface.

```
config system ha
    set ha-mgmt-status enable
    set ha-mgmt-interface port8
    set ha-mgmt-interface-gateway 10.11.101.100
end
```

The reserved management interface default route is not synchronized to other cluster units.

**To change the primary unit reserved management interface configuration - web-based manager**

You can change the IP address of the primary unit reserved management interface from the primary unit web-based manager. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1. From a PC on the internal network, browse to <http://10.11.101.100> and log into the cluster web-based manager.

This logs you into the primary unit web-based manager.

You can identify the primary unit from its serial number or host name that appears on the System Information dashboard widget.

2. Go to *System > Network > Interfaces* and edit the port8 interface as follows:

<b>Alias</b>	primary_reserved
<b>IP/Netmask</b>	10.11.101.101/24
<b>Administrative Access</b>	Ping, SSH, HTTPS, SNMP

3. Select OK.

You can now log into the primary unit web-based manager by browsing to <https://10.11.101.101>. You can also log into this primary unit CLI by using an SSH client to connect to 10.11.101.101.

### **To change subordinate unit reserved management interface configuration - CLI**

At this point you cannot connect to the subordinate unit reserved management interface because it does not have an IP address. Instead, this procedure describes connecting to the primary unit CLI and using the `execute ha manage` command to connect to subordinate unit CLI to change the port8 interface. You can also use a serial connection to the cluster unit CLI. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1. Connect to the primary unit CLI and use the `execute ha manage` command to connect to a subordinate unit CLI.

You can identify the subordinate unit from its serial number or host name. The host name appears in the CLI prompt.

2. Enter the following command to change the port8 IP address to 10.11.101.102 and set management access to HTTPS, ping, SSH, and SNMP.

```
config system interface
  edit port8
    set ip 10.11.101.102/24
    set allowaccess https ping ssh snmp
  end
```

You can now log into the subordinate unit web-based manager by browsing to <https://10.11.101.102>. You can also log into this subordinate unit CLI by using an SSH client to connect to 10.11.101.102.

### **To configure the cluster for SNMP management using the reserved management interfaces - CLI**

This procedure describes how to configure the cluster to allow the SNMP server to get status information from the primary unit and the subordinate unit. The SNMP configuration is synchronized to all cluster units. To support using the reserved management interfaces, you must add at least one HA direct management host to an SNMP community. If your SNMP configuration includes SNMP users with user names and passwords you must also enable HA direct management for SNMP users.

1. Enter the following command to add an SNMP community called `Community` and add a host to the community for the reserved management interface of each cluster unit. The host includes the IP address of the SNMP server (10.11.101.20).

```
config system snmp community
    edit 1
        set name Community
    config hosts
        edit 1
            set ha-direct enable
            set ip 10.11.101.20
        end
    end
end
```

2. Enter the following command to add an SNMP user for the reserved management interface.

```
config system snmp user
    edit 1
        set ha-direct enable
        set notify-hosts 10.11.101.20
    end
```

Configure other settings as required.

### **To get CPU, memory, and network usage of each cluster unit using the reserved management IP addresses**

From the command line of an SNMP manager, you can use the following SNMP commands to get CPU, memory and network usage information for each cluster unit. In the examples, the community name is `Community`. The commands use the MIB field names and OIDs listed in [Table 57 on page 1265](#).

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.101 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.101
1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.101
1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.101
1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.102 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.102
1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.102
1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.102
1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

## The primary unit acts as a router for subordinate unit management traffic

HA uses routing and inter-VDOM links to route subordinate unit management traffic through the primary unit to the network. Similar to a standalone FortiGate unit, subordinate units may generate their own management traffic, including:

- DNS queries.
- FortiGuard Web Filtering rating requests.
- Log messages to be sent to a FortiAnalyzer unit, to a syslog server, or to the FortiGuard Analysis and Management Service.
- Log file uploads to a FortiAnalyzer unit.
- Quarantine file uploads to a FortiAnalyzer unit.
- SNMP traps.
- Communication with remote authentication servers (RADIUS, LDAP, TACACS+ and so on)

Subordinate units send this management traffic over the HA heartbeat link to the primary unit. The primary unit forwards the management traffic to its destination. The primary unit also routes replies back to the subordinate unit in the same way.

HA uses a hidden VDOM called `vsys_ha` for HA operations. The `vsys_ha` VDOM includes the HA heartbeat interfaces, and all communication over the HA heartbeat link goes through the `vsys_ha` VDOM. To provide communication from a subordinate unit to the network, HA adds hidden inter-VDOM links between the primary unit management VDOM and the primary unit `vsys_ha` VDOM. By default, root is the management VDOM.

Management traffic from the subordinate unit originates in the subordinate unit `vsys_ha` VDOM. The `vsys_ha` VDOM routes the management traffic over the HA heartbeat link to the primary unit `vsys_ha` VDOM. This management traffic is then routed to the primary unit management VDOM and from there out onto the network.

DNS queries and FortiGuard Web Filtering and Email Filter requests are still handled by the HA proxy so the primary unit and subordinate units share the same DNS query cache and the same FortiGuard Web Filtering and Email Filter cache. In a virtual clustering configuration, the cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering, Email Filtering, and DNS query cache.

**Figure 205:**Subordinate unit management traffic path

## Cluster communication with RADIUS and LDAP servers

In an active-passive cluster, only the primary unit processes traffic, so the primary unit communicates with RADIUS or LDAP servers. In a cluster that is operating in active-active mode, subordinate units send RADIUS and LDAP requests to the primary unit over the HA heartbeat link and the primary unit routes them to their destination. The primary unit relays the responses back to the subordinate unit.

## Clusters and FortiGuard services

This section describes how various FortiGate HA clustering configurations communicate with the FDN.

In an operating cluster, the primary unit communicates directly with the FortiGuard Distribution Network (FDN). Subordinate units also communicate directly with the FDN but as described in [“The primary unit acts as a router for subordinate unit management traffic” on page 1259](#), all communication between subordinate units and the FDN is routed through the primary unit.

You must register and licence all of the units in a cluster for all required FortiGuard services, both because all cluster units communicate with the FDN and because any cluster unit could potentially become the primary unit.

### FortiGuard and active-passive clusters

For an active-passive cluster, only the primary unit processes traffic. Even so, all cluster units communicate with the FDN. Only the primary unit sends FortiGuard Web Filtering and Antispam requests to the FDN. All cluster units receive FortiGuard Antivirus, IPS, and application control updates from the FDN.

In an active-passive cluster the FortiGuard Web Filter and Email Filter caches are located on the primary unit in the same way as for a standalone FortiGate unit. The caches are not shared among cluster units so after a failover the new primary unit must build up new caches.

In an active-passive cluster all cluster units also communicate with the FortiGuard Analysis and Management Service (FAMS).

### FortiGuard and active-active clusters

For an active-active cluster, both the primary unit and the subordinate units process traffic. Communication between the cluster units and the FDN is the same as for active-passive clusters with the following exception.

Because the subordinate units process traffic, they may also be making FortiGuard Web Filtering and Email Filter requests. The primary unit receives all such requests from the subordinate units and relays them to the FDN and then relays the FDN responses back to the subordinate units. The FortiGuard Web Filtering and Email Filtering URL caches are maintained on the primary unit. The primary unit caches are used for primary and subordinate unit requests.

## FortiGuard and virtual clustering

For a virtual clustering configuration the management virtual domain of each cluster unit communicates with the FDN. The cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering and Email Filtering caches. All FortiGuard Web Filtering and Email Filtering requests are proxied by the management VDOM of the cluster unit that is the primary unit for the management virtual domain.

## Clusters and logging

This section describes the log messages that provide information about how HA is functioning, how to view and manage logs for each unit in a cluster, and provides some example log messages that are recorded during specific cluster events.

You configure logging for a cluster in the same way as you configuring logging for a standalone FortiGate unit. Log configuration changes made to the cluster are synchronized to all cluster units.

All cluster units record log messages separately to the individual cluster unit's log disk, to the cluster unit's system memory, or both. You can view and manage log messages for each cluster unit from the cluster web-based manager Log Access page.

When remote logging is configured, all cluster units send log messages to remote FortiAnalyzer units or other remote servers as configured. HA uses routing and inter-VDOM links to route subordinate unit log traffic through the primary unit to the network. See [“The primary unit acts as a router for subordinate unit management traffic” on page 1259](#).

When you configure a FortiAnalyzer unit to receive log messages from a FortiGate cluster, you should add a cluster to the FortiAnalyzer unit configuration so that the FortiAnalyzer unit can receive log messages from all cluster units.

## Viewing and managing log messages for individual cluster units

This section describes how to view and manage log messages for an individual cluster unit.

### To view HA cluster log messages

1. Log into the cluster web-based manager.
2. Go to *Log&Report > Log Access* and select Memory or Disk.  
For each log display, the *HA Cluster* list displays the serial number of the cluster unit for which log messages are displayed. The serial numbers are displayed in order in the list.
3. Set *HA Cluster* to the serial number of one of the cluster units to display log messages for that unit.

You can view logs saved to memory or logs saved to the hard disk for the cluster unit.

### About HA event log messages

HA event log messages always include the host name and serial number of the cluster unit that recorded the message. HA event log messages also include the HA state of the unit and also

indicate when a cluster unit switches (or moves) from one HA state to another. Cluster units can operate in the HA states listed in [Table 56](#):

**Table 56:** HA states

<b>Hello</b>	A FortiGate unit configured for HA operation has started up and is looking for other FortiGate units with which to form a cluster.
<b>Work</b>	In an active-passive cluster a cluster unit is operating as the primary unit. In an active-active cluster unit is operating as the primary unit or a subordinate unit.
<b>Standby</b>	In an active-passive cluster the cluster unit is operating as a subordinate unit.

HA log Event log messages also indicate the virtual cluster that the cluster unit is operating in as well as the member number of the unit in the cluster. If virtual domains are not enabled, all clusters unit are always operating in virtual cluster 1. If virtual domains are enabled, a cluster unit may be operating in virtual cluster 1 or virtual cluster 2. The member number indicates the position of the cluster unit in the cluster members list. Member 0 is the primary unit. Member 1 is the first subordinate unit, member 2 is the second subordinate unit, and so on.

## HA log messages

See the [FortiGate Log Message Reference](#) for a listing of and descriptions of the HA log messages.

## Fortigate HA message "HA master heartbeat interface <intf\_name> lost neighbor information"

The following HA log messages may be recorded by an operating cluster:

```
2009-02-16 11:06:34 device_id=FG2001111111 log_id=0105035001 type=event
subtype=ha pri=critical vd=root msg="HA slave heartbeat interface internal lost neighbor
information"
```

```
2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event
subtype=ha pri=notice vd=root msg="Virtual cluster 1 of group 0 detected new joined HA
member"
```

```
2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event
subtype=ha pri=notice vd=root msg="HA master heartbeat interface internal get peer
information"
```

These log messages indicate that the cluster units could not connect to each other over the HA heartbeat link for the period of time that is given by hb-interval x hb-lost-threshold, which is 1.2 seconds with the default values.

### To diagnose this problem

1. Check all heartbeat interface connections including cables and switches to make sure they are connected and operating normally.
2. Use the following commands to display the status of the heartbeat interfaces.

```
get hardware nic <heartbeat_interface_name>
diagnose hardware deviceinfo nic <heartbeat_interface_name>
```

The status information may indicate the interface status and link status and also indicate if a large number of errors have been detected.

3. If the log message only appears during peak traffic times, increase the tolerance for missed HA heartbeat packets by using the following commands to increase the lost heartbeat threshold and heartbeat interval:

```
config system ha
    set hb-lost-threshold 12
    set hb-interval 4
end
```

These settings multiply by 4 the loss detection interval. You can use higher values as well.

This condition can also occur if the cluster units are located in different buildings or even different geographical locations. Called a distributed cluster, as a result of the separation it may take a relatively long time for heartbeat packets to be transmitted between cluster units. You can support a distributed cluster by increasing the heartbeat interval so that the cluster expects extra time between heartbeat packets.

4. Optionally disable session-pickup to reduce the processing load on the heartbeat interfaces.
5. Instead of disabling session-pickup you can enable `session-pickup-delay` to reduce the number of sessions that are synchronized. With this option enabled only sessions that are active for more than 30 seconds are synchronized.

It may be useful to monitor CPU and memory usage to check for low memory and high CPU usage. You can configure event logging to monitor CPU and memory usage. You can also enable the CPU over usage and memory low SNMP events.

Once this monitoring is in place, try and determine if there have been any changes in the network or an increase of traffic recently that could be the cause. Check to see if the problem happens frequently and if so what the pattern is.

To monitor the CPU of the cluster units and troubleshoot further, use the following procedure and commands:

```
get system performance status
get sys performance top 2
diagnose sys top 2
```

These commands repeated at frequent intervals will show the activity of the CPU and the number of sessions.

Search the [Fortinet Knowledge Base](#) for articles about monitoring CPU and Memory usage.

If the problem persists, gather the following information (a console connection might be necessary if connectivity is lost) and provide it to Technical Support when opening a ticket:

- Debug log from the web-based manager: *System > Config > Advanced > Download Debug Log*
- CLI command output:

```
diag sys top 2 (keep it running for 20 seconds)
get sys perf status (repeat this command multiple times to get good samples)
get sys ha status
diagnose sys ha status
diagnose sys ha dump-by {all options}
diagnose netlink device list
diagnose hardware deviceinfo nic <heartbeat-interface-name>
execute log filter category 1
execute log display
```

## Formatting cluster unit hard disks (log disks)

If you need to format the hard disk (also called log disk or disk storage) of one or more cluster units you should disconnect the unit from the cluster and use the `execute formatlogdisk` command to format the cluster unit hard disk then add the unit back to the cluster.

For information about how to remove a unit from a cluster and add it back, see [“Disconnecting a cluster unit from a cluster” on page 1285](#) and [“Adding a disconnected FortiGate unit back to its cluster” on page 1286](#).

Once you add the cluster unit with the formatted log disk back to the cluster you should make it the primary unit before removing other units from the cluster to format their log disks and then add them back to the cluster.

## Clusters and SNMP

You can use SNMP to manage a cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration and status information and receive traps.

You configure SNMP for a cluster in the same way as configuring SNMP for a standalone FortiGate unit. SNMP configuration changes made to the cluster are shared by all cluster units.

Each cluster unit sends its own traps and SNMP manager systems can use SNMP get commands to query each cluster unit separately. To set SNMP get queries to each cluster unit you must create a special get command that includes the serial number of the cluster unit.

Alternatively you can use the HA reserved management interface feature to give each cluster unit a different management IP address. Then you can create an SNMP get command for each cluster unit that just includes the management IP address and does not have to include the serial number. See [“Managing individual cluster units using a reserved management interface” on page 1254](#).

For a list of HA MIB fields and OIDs, see [“Fortinet MIBs” on page 1520](#).

## SNMP get command syntax for the primary unit

Normally, to get configuration and status information for a standalone FortiGate unit or for a primary unit, an SNMP manager would use an SNMP get commands to get the information in a MIB field. The SNMP get command syntax would be similar to the following:

```
snmpget -v2c -c <community_name> <address_ipv4> {<OID> | <MIB_field>}
```

where:

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. The most commonly used community name is `public`.

`<address_ipv4>` is the IP address of the FortiGate interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself. The HA MIB fields and OIDs are listed in [Table 57](#).

**Table 57:** SNMP field names and OIDs

<b>MIB field</b>	<b>OID</b>	<b>Description</b>
fgHaSystemMode	.1.3.6.1.4.1.12356.101.13.1.1.0	HA mode (standalone, a-a, or a-p)
fgHaGroupId	.1.3.6.1.4.1.12356.101.13.1.2.0	The HA priority of the cluster unit. Default 128.
fgHaPriority	.1.3.6.1.4.1.12356.101.13.1.3.0	The HA priority of the cluster unit. Default 128.
fgHaOverride	.1.3.6.1.4.1.12356.101.13.1.4.0	Whether HA override is disabled or enabled for the cluster unit.
fgHaAutoSync	.1.3.6.1.4.1.12356.101.13.1.5.0	Whether automatic HA synchronization is disabled or enabled.
fgHaSchedule	.1.3.6.1.4.1.12356.101.13.1.6.0	The HA load balancing schedule. Set to none unless operating in a-p mode.
fgHaGroupName	.1.3.6.1.4.1.12356.101.13.1.7.0	The HA group name.
fgHaStatsIndex	.1.3.6.1.4.1.12356.101.13.2.1.1.1.1	The cluster index of the cluster unit. 1 for the primary unit, 2 to x for the subordinate units.
fgHaStatsSerial	.1.3.6.1.4.1.12356.101.13.2.1.1.2.1	The serial number of the cluster unit.
fgHaStatsCpuUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.3.1	The cluster unit's current CPU usage.
fgHaStatsMemUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.4.1	The cluster unit's current Memory usage.
fgHaStatsNetUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.5.1	The cluster unit's current Network bandwidth usage.
fgHaStatsSesCount	.1.3.6.1.4.1.12356.101.13.2.1.1.6.1	The cluster unit's current session count.
fgHaStatsPktCount	.1.3.6.1.4.1.12356.101.13.2.1.1.7.1	The cluster unit's current packet count.
fgHaStatsByteCount	.1.3.6.1.4.1.12356.101.13.2.1.1.8.1	The cluster unit's current byte count.
fgHaStatsIdsCount	.1.3.6.1.4.1.12356.101.13.2.1.1.9.1	The number of attacks reported by the IPS for the cluster unit.

**Table 57:** SNMP field names and OIDs

MIB field	OID	Description
fgHaStatsAvCount	.1.3.6.1.4.1.12356.101.13.2.1.1.10.1	The number of viruses reported by the antivirus system for the cluster unit.
fgHaStatsHostname	.1.3.6.1.4.1.12356.101.13.2.1.1.11.1	The hostname of the cluster unit.

**To get the HA priority for the primary unit**

The following SNMP get command gets the HA priority for the primary unit. The community name is `public`. The IP address of the cluster interface configured for SNMP management access is 10.10.10.1. The HA priority MIB field is `fgHaPriority` and the OID for this MIB field is 1.3.6.1.4.1.12356.101.13.1.3.0. The first command uses the MIB field name and the second uses the OID:

```
snmpget -v2c -c public 10.10.10.1 fgHaPriority
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.1.3.0
```

**SNMP get command syntax for any cluster unit**

To get configuration status information for a specific cluster unit (for the primary unit or for any subordinate unit), the SNMP manager must add the serial number of the cluster unit to the SNMP get command after the community name. The community name and the serial number are separated with a dash. The syntax for this SNMP get command would be:

```
snmpget -v2c -c <community_name>-<fgt_serial> <address_ipv4> {<OID> | <MIB_field>}
```

where:

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. All units in the cluster have the same community name. The most commonly used community name is `public`.

`<fgt_serial>` is the serial number of any cluster unit. For example, FGT4002803033172. You can specify the serial number of any cluster unit, including the primary unit, to get information for that unit.

`<address_ipv4>` is the IP address of the FortiGate interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself. To find OIDs and MIB field names see [“Fortinet MIBs” on page 1520](#).

If the serial number matches the serial number of a subordinate unit, the SNMP get request is sent over the HA heartbeat link to the subordinate unit. After processing the request, the subordinate unit sends the reply back over the HA heartbeat link back to the primary unit. The primary unit then forwards the response back to the SNMP manager.

If the serial number matches the serial number of the primary unit, the SNMP get request is processed by the primary unit. You can actually add a serial number to the community name of any SNMP get request. But normally you only need to do this for getting information from a subordinate unit.

## To get the CPU usage for a subordinate unit

The following SNMP get command gets the CPU usage for a subordinate unit in a FortiGate-5001SX cluster. The subordinate unit has serial number FG50012205400050. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1. The HA status table MIB field is `fgHaStatsCpuUsage` and the OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.3.1. The first command uses the MIB field name and the second uses the OID for this table:

```
snmpget -v2c -c public-FG50012205400050 10.10.10.1 fgHaStatsCpuUsage
snmpget -v2c -c public-FG50012205400050 10.10.10.1
1.3.6.1.4.1.12356.101.13.2.1.1.3.1
```

FortiGate SNMP recognizes the community name with syntax `<community_name>-<fgt_serial>`. When the primary unit receives an SNMP get request that includes the community name followed by serial number, the FGCP extracts the serial number from the request. Then the primary unit redirects the SNMP get request to the cluster unit with that serial number. If the serial number matches the serial number of the primary unit, the SNMP get is processed by the primary unit.

## Getting serial numbers of cluster units

The following SNMP get commands use the MIB field name `fgHaStatsSerial.<index>` to get the serial number of each cluster unit. Where `<index>` is the cluster unit's cluster index and 1 is the cluster index of the primary unit, 2 is the cluster index of the first subordinate unit, and 3 is the cluster index of the second subordinate unit.

The OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.2.1. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1.

The first command uses the MIB field name and the second uses the OID for this table and gets the serial number of the primary unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.1
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.1.1.2.1
```

The second command uses the MIB field name and the second uses the OID for this table and gets the serial number of the first subordinate unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.2
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.2.2
```

## SNMP get command syntax - reserved management interface enabled

To get configuration and status information for any cluster unit where you have enabled the HA reserved management interface feature and assigned IP addresses to the management interface of each cluster unit, an SNMP manager would use the following get command syntax:

```
snmpget -v2c -c <community_name> <mgt_address_ipv4> {<OID> |
<MIB_field>}
```

where:

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community names to a FortiGate SNMP configuration. The most commonly used community name is `public`.

`<mgt_address_ipv4>` is the IP address of the FortiGate HA reserved management interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself. To find OIDs and MIB field names see your FortiGate unit's online help.

See [“To get CPU, memory, and network usage of each cluster unit using the reserved management IP addresses” on page 1258.](#)

## Clusters and file quarantine

You can configure file quarantine for a cluster in the same way as configuring file quarantine for a standalone FortiGate unit. Quarantine configuration changes made to the cluster are shared by all cluster units.

In an active-active cluster, both the primary unit and the subordinate units accept antivirus sessions and may quarantine files. In an active-passive cluster, only the primary unit quarantines files. Multiple cluster units in an active-passive cluster may have quarantined files if different cluster units have been the primary unit.

All cluster units quarantine files separately to their own hard disk. You can go to *Log&Report > Archive Access > Quarantine* to view and manage the quarantine file list for each cluster unit.

All cluster units can also quarantine files to a FortiAnalyzer unit. When you configure a FortiAnalyzer unit to receive quarantine files from a cluster, you should add each cluster unit to the FortiAnalyzer device configuration so that the FortiAnalyzer unit can receive quarantine files from all cluster units.

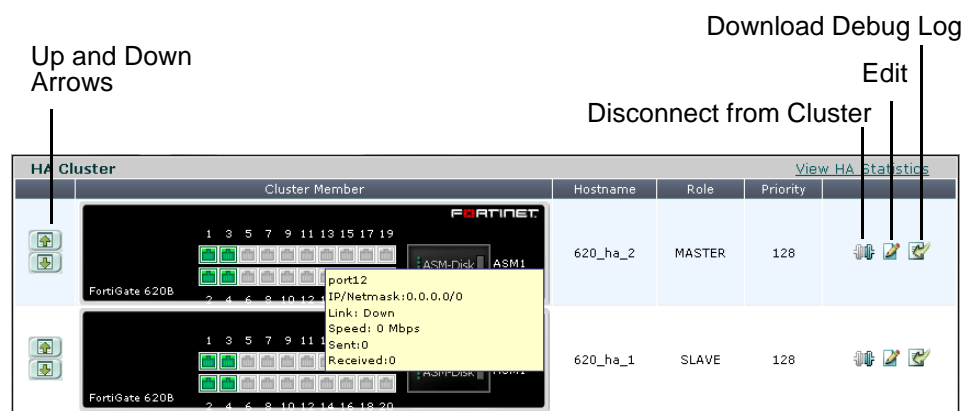

## Cluster members list

Display the cluster members list to view the status of the FortiGate units in an operating cluster. To display the cluster members list, go to *System > Config > HA*.

From the cluster members list you can also:

- View HA statistics (see [“Viewing HA statistics” on page 1271](#)).
- View and optionally change the HA configuration of the operating cluster (see [“Changing the HA configuration of an operating cluster” on page 1273](#)).
- View and optionally change the host name and device priority of a subordinate unit (see [“Changing the subordinate unit host name and device priority” on page 1273](#)).
- Disconnect a cluster unit from a cluster (see [“Disconnecting a cluster unit from a cluster” on page 1285](#)).
- Download the Debug log for any cluster unit. You can send this debug log file to Fortinet Technical Support to help diagnose problems with the cluster or with individual cluster units.

**Figure 206:**Example cluster members list

<b>View HA Statistics</b>	Display the serial number, status, and monitor information for each cluster unit. See <a href="#">“Viewing HA statistics” on page 1271</a> .
<b>Up and down arrows</b>	Change the order in which cluster members are listed. The operation of the cluster or of the units in the cluster are not affected. All that changes is the order in which cluster units are displayed on the cluster members list.
<b>Cluster member</b>	Illustrations of the front panels of the cluster units. If the network jack for an interface is shaded green, the interface is connected. Pause the mouse pointer over each illustration to view the cluster unit host name, serial number, and how long the unit has been operating (up time). The list of monitored interfaces is also displayed.
<b>Hostname</b>	<p>The host name of the FortiGate unit. The default host name of the FortiGate unit is the FortiGate unit serial number.</p> <ul style="list-style-type: none"> <li>To change the primary unit host name, go to the system dashboard and select Change beside the current host name in System Information widget.</li> <li>To change a subordinate unit host name, from the cluster members list select the edit icon for a subordinate unit.</li> </ul>
<b>Role</b>	<p>The status or role of the cluster unit in the cluster.</p> <ul style="list-style-type: none"> <li>Role is MASTER for the primary (or master) unit</li> <li>Role is SLAVE for all subordinate (or backup) cluster units</li> </ul>
<b>Priority</b>	<p>The device priority of the cluster unit. Each cluster unit can have a different device priority. During HA negotiation, the unit with the highest device priority becomes the primary unit.</p> <p>The device priority range is 0 to 255. The default device priority is 128.</p>
<b>Disconnect from cluster</b>	Disconnect the cluster unit from the cluster. See <a href="#">“Disconnecting a cluster unit from a cluster” on page 1285</a> .

<b>Edit</b>	<p>Select Edit to change a cluster unit HA configuration.</p> <ul style="list-style-type: none"> <li>• For a primary unit, select Edit to change the cluster HA configuration. You can also change the device priority of the primary unit.</li> <li>• For a primary unit in a virtual cluster, select Edit to change the virtual cluster HA configuration. You can also change the virtual cluster 1 and virtual cluster 2 device priority of this cluster unit.</li> <li>• For a subordinate unit, select Edit to change the subordinate unit host name and device priority. See <a href="#">“Changing the subordinate unit host name and device priority” on page 1273</a>.</li> <li>• For a subordinate unit in a virtual cluster, select Edit to change the subordinate unit host name. In addition you can change the device priority for the subordinate unit for the selected virtual cluster.</li> </ul>
<b>Download debug log</b>	<p>Download an encrypted debug log to a file. You can send this debug log file to Fortinet Technical Support to help diagnose problems with the cluster or with individual cluster units.</p>

## Virtual cluster members list

If virtual domains are enabled, you can display the cluster members list to view the status of the operating virtual clusters. The virtual cluster members list shows the status of both virtual clusters including the virtual domains added to each virtual cluster.

To display the virtual cluster members list for an operating cluster log in as the admin administrator, select Global Configuration and go to *System > Config > HA*.

**Figure 207:**Example FortiGate-5001SX virtual cluster members list

Up and Down Arrows

Disconnect from Cluster

Edit

Download Debug Log

Cluster Member	Hostname	Role	Priority
FortiGate 620B	620_ha_2	MASTER	128
FortiGate 620B	620_ha_1	SLAVE	128

The fields and functions of the virtual cluster members list are the same as the fields and functions described in “[Cluster members list](#)” on page 1268 with the following exceptions.

- When you select the edit icon for a primary unit in a virtual cluster, you can change the virtual cluster 1 and virtual cluster 2 device priority of this cluster unit and you can edit the VDOM partitioning configuration of the cluster.
- When you select the edit icon for a subordinate unit in a virtual cluster, you can change the device priority for the subordinate unit for the selected virtual cluster.

Also, the HA cluster members list changes depending on the cluster unit. For the virtual cluster described in the “[Example: virtual clustering with two VDOMs and VDOM partitioning](#)” on page 1221 if you connect to port5 using you are connecting to 620b\_ha\_2 (620b\_ha\_2 is displayed on the web browser title bar or in the CLI prompt).

If you connect to port1 you are connecting to 620b\_ha\_1 (620b\_ha\_2 is displayed on the web browser title bar or in the CLI prompt).

## Viewing HA statistics

From the cluster members list you can select View HA statistics to display the serial number, status, and monitor information for each cluster unit. To view HA statistics, go to *System > Config > HA* and select View HA Statistics.

**Figure 208:**Example HA statistics (active-passive cluster)

Refresh every		<div><div></div>none</div>	<a href="#">Back to HA monitor &gt;&gt;</a>			
Unit	Status	Up Time	Monitor			
620_ha_2 FG600B3908600825	<div><div></div></div>	5 days	CPU Usage	Active Sessions	Total Packets	Virus Detected
		22 hours	<div><div></div>0%</div>	42	74875	0
		57 minutes	Memory Usage	Network Utilization	Total Bytes	Intrusion Detected
		17 seconds	<div><div></div>10%</div>	30 Kbps	26981277	0
620_ha_1 FG600B3908600705	<div><div></div></div>	5 days	CPU Usage	Active Sessions	Total Packets	Virus Detected
		22 hours	<div><div></div>0%</div>	21	12115	0
		48 minutes	Memory Usage	Network Utilization	Total Bytes	Intrusion Detected
		58 seconds	<div><div></div>10%</div>	19 Kbps	930358	0

<b>Refresh every</b>	Select to control how often the web-based manager updates the HA statistics display.
<b>Back to HA monitor</b>	Close the HA statistics list and return to the cluster members list.
<b>Serial No.</b>	Use the serial number ID to identify each FortiGate unit in the cluster. The cluster ID matches the FortiGate unit serial number.
<b>Status</b>	Indicates the status of each cluster unit. A green check mark indicates that the cluster unit is operating normally. A red X indicates that the cluster unit cannot communicate with the primary unit.
<b>Up Time</b>	The time in days, hours, minutes, and seconds since the cluster unit was last started.
<b>Monitor</b>	Displays system status information for each cluster unit.
<b>CPU Usage</b>	The current CPU status of each cluster unit. The web-based manager displays CPU usage for core processes only. CPU usage for management processes (for example, for HTTPS connections to the web-based manager) is excluded.
<b>Memory Usage</b>	The current memory status of each cluster unit. The web-based manager displays memory usage for core processes only. Memory usage for management processes (for example, for HTTPS connections to the web-based manager) is excluded.
<b>Active Sessions</b>	The number of communications sessions being processed by the cluster unit.
<b>Total Packets</b>	The number of packets that have been processed by the cluster unit since it last started up.
<b>Virus Detected</b>	The number of viruses detected by the cluster unit.
<b>Network Utilization</b>	The total network bandwidth being used by all of the cluster unit interfaces.

<b>Total Bytes</b>	The number of bytes that have been processed by the cluster unit since it last started up.
<b>Intrusion Detected</b>	The number of intrusions or attacks detected by Intrusion Protection running on the cluster unit.

## Changing the HA configuration of an operating cluster

To change the configuration settings of an operating cluster, go to *System > Config > HA* to display the cluster members list. Select Edit for the master (or primary) unit in the cluster members list to display the HA configuration page for the cluster.

You can use the HA configuration page to check and fine tune the configuration of the cluster after the cluster is up and running. For example, if you connect or disconnect cluster interfaces you may want to change the Port Monitor configuration.

Any changes you make on this page, with the exception of changes to the device priority, are first made to the primary unit configuration and then synchronized to the subordinate units. Changing the device priority only affects the primary unit.

## Changing the HA configuration of an operating virtual cluster

To change the configuration settings of the primary unit in a functioning cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to *System > Config > HA* to display the cluster members list. Select Edit for the master (or primary) unit in virtual cluster 1 or virtual cluster 2 to display the HA configuration page for the virtual cluster.

You can use the virtual cluster HA configuration page to check and fine tune the configuration of both virtual clusters after the cluster is up and running. For example, you may want to change the Port Monitor configuration for virtual cluster 1 and virtual cluster 2 so that each virtual cluster monitors its own interfaces.

You can also use this configuration page to move virtual domains between virtual cluster 1 and virtual cluster 2. Usually you would distribute virtual domains between the two virtual clusters to balance the amount of traffic being processed by each virtual cluster.

Any changes you make on this page, with the exception of changes to the device priorities, are first made to the primary unit configuration and then synchronized to the subordinate unit.

You can also adjust device priorities to configure the role of this cluster unit in the virtual cluster. For example, to distribute traffic to both cluster units in the virtual cluster configuration, you would want one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. You can create this configuration by setting the device priorities. The cluster unit with the highest device priority in virtual cluster 1 becomes the primary unit for virtual cluster 1. The cluster unit with the highest device priority in virtual cluster 2 becomes the primary unit in virtual cluster 2.

## Changing the subordinate unit host name and device priority

To change the host name and device priority of a subordinate unit in an operating cluster, go to *System > Config > HA* to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

To change the host name and device priority of a subordinate unit in an operating cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to *System > Config > HA* to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

You can change the host name (Peer) and device priority (Priority) of this subordinate unit. These changes only affect the configuration of the subordinate unit.

The device priority is not synchronized among cluster members. In a functioning cluster you can change device priority to change the priority of any unit in the cluster. The next time the cluster negotiates, the cluster unit with the highest device priority becomes the primary unit.

The device priority range is 0 to 255. The default device priority is 128.

## Upgrading cluster firmware

You can upgrade the FortiOS firmware running on an HA cluster in the same manner as upgrading the firmware running on a standalone FortiGate unit. During a normal firmware upgrade, the cluster upgrades the primary unit and all subordinate units to run the new firmware image. The firmware upgrade takes place without interrupting communication through the cluster.

Upgrading cluster firmware to a new major release (for example upgrading from 3.0 MRx to 4.0 MRx) is supported for clusters. Make sure you are taking an upgrade path described in the release notes. Even so you should back up your configuration and only perform such a firmware upgrade during a maintenance window.

---

To upgrade the firmware without interrupting communication through the cluster, the cluster goes through a series of steps that involve first upgrading the firmware running on the subordinate units, then making one of the subordinate units the primary unit, and finally upgrading the firmware on the former primary unit. These steps are transparent to the user and the network, but depending upon your HA configuration may result in the cluster selecting a new primary unit.

The following sequence describes in detail the steps the cluster goes through during a firmware upgrade and how different HA configuration settings may affect the outcome.

1. The administrator uploads a new firmware image from the web-based manager or CLI.
2. If the cluster is operating in active-active mode load balancing is turned off.
3. The cluster upgrades the firmware running on all of the subordinate units.
4. Once the subordinate units have been upgraded, a new primary unit is selected.

This primary unit will be running the new upgraded firmware.

5. The cluster now upgrades the firmware of the former primary unit.

If the age of the new primary unit is more than 300 seconds (5 minutes) greater than the age of all other cluster units, the new primary unit continues to operate as the primary unit.

This is the intended behavior but does not usually occur because the age difference of the cluster units is usually less than the cluster age difference margin of 300 seconds. So instead, the cluster negotiates again to select a primary unit as described in [“Primary unit selection” on page 1131](#).

You can keep the cluster from negotiating again by reducing the cluster age difference margin using the `ha-uptime-diff-margin` option. However, you should be cautious when reducing the age or other problems may occur. For information about the cluster age difference margin, see [“Cluster age difference margin \(grace period\)” on page 1133](#). For

more information about changing the cluster age margin, see [“Changing the cluster age difference margin” on page 1133](#).

6. If the cluster is operating in active-active mode, load balancing is turned back on.

## Changing how the cluster processes firmware upgrades

By default cluster firmware upgrades proceed as uninterruptible upgrades that do not interrupt traffic flow. If required, you can use the following CLI command to change how the cluster handles firmware upgrades. You might want to change this setting if you are finding uninterruptible upgrades take too much time.

```
config system ha
    set uninterruptible-upgrade disable
end
```

`uninterruptible-upgrade` is enabled by default. If you disable `uninterruptible-upgrade` the cluster still upgrades the firmware on all cluster units, but all cluster units are upgraded at once; which takes less time but interrupts communication through the cluster.

## Synchronizing the firmware build running on a new cluster unit

If the firmware build running on a FortiGate unit that you add to a cluster is older than the cluster firmware build, you may be able to use the following steps to synchronize the firmware running on the new cluster unit.

This procedure describes re-installing the same firmware build on a cluster to force the cluster to upgrade all cluster units to the same firmware build.

Due to firmware upgrade and synchronization issues, in some cases this procedure may not work. In all cases it will work to install the same firmware build on the new unit as the one that the cluster is running before adding the new unit to the cluster.

### To synchronize the firmware build running on a new cluster unit

1. Obtain a firmware image that is the same as build already running on the cluster.
2. Connect to the cluster using the web-based manager.
3. Go to the *System Information* dashboard widget.
4. Select *Update* beside *Firmware Version*.  
You can also install a newer firmware build.
5. Select OK.

After the firmware image is uploaded to the cluster, the primary unit upgrades all cluster units to this firmware build.

## Downgrading cluster firmware

For various reasons you may need to downgrade the firmware that a cluster is running. You can use the information in this section to downgrade the firmware version running on a cluster.

In most cases you can downgrade the firmware on an operating cluster using the same steps as for a firmware upgrade. A warning message appears during the downgrade but the downgrade usually works and after the downgrade the cluster continues operating normally with the older firmware image.

Downgrading between some firmware versions, especially if features have changed between the two versions, may not always work without the requirement to fix configuration issues after the downgrade.

Only perform firmware downgrades during maintenance windows and make sure you back up your cluster configuration before the downgrade.

If the firmware downgrade that you are planning may not work without configuration loss or other problems, you can use the following downgrade procedure to make sure your configuration is not lost after the downgrade.

### To downgrade cluster firmware

This example shows how to downgrade the cluster shown in [Figure 190 on page 1153](#). The cluster consists of two cluster units (620\_ha\_1 and 620\_ha\_2). The port1 and port2 interfaces are connected networks and the port3 and port4 interfaces are connected together for the HA heartbeat.

This example, describes separating each unit from the cluster and downgrading the firmware for the standalone FortiGate units. There are several ways you could disconnect units from the cluster. This example describes using the disconnect from cluster function described in [“Disconnecting a cluster unit from a cluster” on page 1285](#).

1. Go to the *System Information* dashboard widget and backup the cluster configuration.

From the CLI use `execute backup config`.

2. Go to *System > Config > HA* and for 620\_ha\_1 select the *Disconnect from cluster* icon.
3. Select the port2 interface and enter an IP address and netmask of 10.11.101.101/24 and select OK.

From the CLI you can enter the following command (FG600B3908600705 is the serial number of the cluster unit) to be able to manage the standalone FortiGate unit by connecting to the port2 interface with IP address and netmask 10.11.101.101/24.

```
execute ha disconnect FG600B3908600705 port2 10.11.101.101/24
```

After 620\_ha\_1 is disconnected, 620\_ha\_2 continues processing traffic.

4. Connect to the 620\_ha\_1 web-based manager or CLI using IP address 10.11.101.101/24 and follow normal procedures to downgrade standalone FortiGate unit firmware.
5. When the downgrade is complete confirm that the configuration of 620\_ha\_1 is correct.
6. Set the HA mode of 620\_ha\_2 to Standalone and follow normal procedures to downgrade standalone FortiGate unit firmware.

Network communication will be interrupted for a short time during the downgrade.

7. When the downgrade is complete confirm that the configuration of 620\_ha\_2 is correct.
8. Set the HA mode of 620\_ha\_2 to Active-Passive or the required HA mode.
9. Set the HA mode of 620\_ha\_1 to the same mode as 620\_ha\_2.

If you have not otherwise changed the HA settings of the cluster units and if the firmware downgrades have not affected the configurations the units should negotiate and form cluster running the downgraded firmware.

## Backing up and restoring the cluster configuration

You can backup the configuration of the primary unit by logging into the web-based manager or CLI and following normal configuration backup procedures.

The following configuration settings are not synchronized to all cluster units:

- HA override and priority
- The interface configuration of the HA reserved management interface (`config system interface`)
- The HA reserved management interface default route (`ha-mgmt-interface-gateway`)
- The FortiGate unit host name.

To backup these configuration settings for each cluster unit you must log into each cluster unit and backup its configuration.

If you need to restore the configuration of the cluster including the configuration settings that are not synchronized you should first restore the configuration of the primary unit and then restore the configuration of each cluster unit. Alternatively you could log into each cluster unit and manually add the configuration settings that were not restored.

## Monitoring cluster units for failover

If the primary unit in the cluster fails, the units in the cluster renegotiate to select a new primary unit. Failure of the primary unit results in the following:

- If SNMP is enabled, the new primary unit sends HA trap messages. The messages indicate a cluster status change, HA heartbeat failure, and HA member down. For more info about HA and SNMP, see [“Clusters and SNMP” on page 1264](#).
- If event logging is enabled and HA activity event is selected, the new primary unit records log messages that show that the unit has become the primary unit.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGate units. The failed primary unit no longer appears on the Cluster Members list.
- The host name and serial number of the primary unit changes. You can see these changes when you log into the web-based manager or CLI.
- The cluster info displayed on the dashboard, cluster members list or from the `get system ha status` command changes.

If a subordinate unit fails, the cluster continues to function normally. Failure of a subordinate unit results in the following:

- If event logging is enabled and HA activity event is selected, the primary unit records log messages that show that a subordinate has been removed from the cluster.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGate units. The failed unit no longer appears on the Cluster Members list.

## Viewing cluster status from the CLI

Use the `get system ha status` command to display information about an HA cluster. The command displays general HA configuration settings. The command also displays information about how the cluster unit that you have logged into is operating in the cluster.

Usually you would log into the primary unit CLI using SSH or telnet. In this case the `get system ha status` command displays information about the primary unit first, and also displays the HA state of the primary unit (the primary unit operates in the work state). However,

if you log into the primary unit and then use the `execute ha manage` command to log into a subordinate unit, (or if you use a console connection to log into a subordinate unit) the `get system status` command displays information about this subordinate unit first, and also displays the HA state of this subordinate unit. The state of a subordinate unit is work for an active-active cluster and standby for an active-passive cluster.

For a virtual cluster configuration, the `get system ha status` command displays information about how the cluster unit that you have logged into is operating in virtual cluster 1 and virtual cluster 2. For example, if you connect to the cluster unit that is the primary unit for virtual cluster 1 and the subordinate unit for virtual cluster 2, the output of the `get system ha status` command shows virtual cluster 1 in the work state and virtual cluster 2 in the standby state. The `get system ha status` command also displays additional information about virtual cluster 1 and virtual cluster 2.

The command display includes the following fields.

Fields	Description
Model	The FortiGate model number.
Mode	The HA mode of the cluster: a-a or a-p.
Group	The group ID of the cluster.
Debug	The debug status of the cluster.
ses_pickup	The status of session pickup: enable or disable.
load balance	The status of the <code>load-balance-all</code> keyword: enable or disable. Relevant to active-active clusters only.
schedule	The active-active load balancing schedule. Relevant to active-active clusters only.
Master Slave	<p><b>Master</b> displays the device priority, host name, serial number, and cluster index of the primary (or master) unit.</p> <p><b>Slave</b> displays the device priority, host name, serial number, and cluster index of the subordinate (or slave, or backup) unit or units.</p> <p>The list of cluster units changes depending on how you log into the CLI. Usually you would use SSH or telnet to log into the primary unit CLI. In this case the primary unit would be at the top the list followed by the other cluster units.</p> <p>If you use <code>execute ha manage</code> or a console connection to log into a subordinate unit CLI, and then enter <code>get system ha status</code> the subordinate unit that you have logged into appears at the top of the list of cluster units.</p>
number of vcluster	The number of virtual clusters. If virtual domains are not enabled, the cluster has one virtual cluster. If virtual domains are enabled the cluster has two virtual clusters.

Fields	Description
vcluster 1 Master Slave	<p>The HA state (hello, work, or standby) and HA heartbeat IP address of the cluster unit that you have logged into in virtual cluster 1. If virtual domains are not enabled, <code>vcluster 1</code> displays information for the cluster. If virtual domains are enabled, <code>vcluster 1</code> displays information for virtual cluster 1.</p> <p>The HA heartbeat IP address is 169.254.0.2 if you are logged into the primary unit of virtual cluster 1 and 169.254.0.1 if you are logged into a subordinate unit of virtual cluster 1.</p> <p><code>vcluster 1</code> also lists the primary unit (master) and subordinate units (slave) in virtual cluster 1. The list includes the cluster index and serial number of each cluster unit in virtual cluster 1. The cluster unit that you have logged into is at the top of the list.</p> <p>If virtual domains are not enabled and you connect to the primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the primary unit.</p> <p>If virtual domains are not enabled and you connect to a subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you have logged into.</p> <p>If virtual domains are enabled and you connect to the virtual cluster 1 primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the virtual cluster 1 primary unit.</p> <p>If virtual domains are enabled and you connect to the virtual cluster 1 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you are logged into.</p>
vcluster 2 Master Slave	<p><code>vcluster 2</code> only appears if virtual domains are enabled.</p> <p><code>vcluster 2</code> displays the HA state (hello, work, or standby) and HA heartbeat IP address of the cluster unit that you have logged into in virtual cluster 2. The HA heartbeat IP address is 169.254.0.2 if you are logged into the primary unit of virtual cluster 2 and 169.254.0.1 if you are logged into a subordinate unit of virtual cluster 2.</p> <p><code>vcluster 2</code> also lists the primary unit (master) and subordinate units (slave) in virtual cluster 2. The list includes the cluster index and serial number of each cluster unit in virtual cluster 2. The cluster unit that you have logged into is at the top of the list.</p> <p>If you connect to the virtual cluster 2 primary unit CLI, the HA state of the cluster unit in virtual cluster 2 is <code>work</code>. The display lists the cluster units starting with the virtual cluster 2 primary unit.</p> <p>If you connect to the virtual cluster 2 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 2 is <code>standby</code>. The display lists the cluster units starting with the subordinate unit that you are logged into.</p>

## Examples

The following example shows `get system ha status` output for a cluster of two FortiGate-5001SX units operating in active-active mode. The cluster group ID, session pickup, load balance all, and the load balancing schedule are all set to the default values. The device

priority of the primary unit is also set to the default value. The device priority of the subordinate unit has been reduced to 100. The host name of the primary unit is 5001\_Slot\_4. The host name of the subordinate unit is 5001\_Slot\_3.

The command output was produced by connecting to the primary unit CLI (host name 5001\_Slot\_4).

```
Model: 5000
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
load_balance: disable
schedule: round robin
Master:128 5001_Slot_4      FG50012204400045 1
Slave :100 5001_Slot_3      FG50012205400050 0
number of vcluster: 1
vcluster 1: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050
```

The following command output was produced by using `execute HA manage 0` to log into the subordinate unit CLI of the cluster shown in the previous example. The host name of the subordinate unit is 5001\_Slot\_3.

```
Model: 5000
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
load_balance: disable
schedule: round robin
Slave :100 5001_Slot_3      FG50012205400050 0
Master:128 5001_Slot_4      FG50012204400045 1
number of vcluster: 1
vcluster 1: work 169.254.0.2
Slave :1 FG50012205400050
Master:0 FG50012204400045
```

The following example shows `get system ha status` output for a cluster of three FortiGate-5001 units operating in active-passive mode. The cluster group ID is set to 20 and session pickup is enabled. Load balance all and the load balancing schedule are set to the default value. The device priority of the primary unit is set to 200. The device priorities of the subordinate units are set to 128 and 100. The host name of the primary unit is 5001\_Slot\_5. The host names of the subordinate units are 5001\_Slot\_3 and 5001\_Slot\_4.

```
Model: 5000
Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Master:200 5001_Slot_5      FG50012206400112 0
Slave :100 5001_Slot_3      FG50012205400050 1
Slave :128 5001_Slot_4      FG50012204400045 2
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG50012206400112
Slave :1 FG50012204400045
```

```
Slave :2 FG50012205400050
```

The following example shows `get system ha status` output for a cluster of two FortiGate-5001 units with virtual clustering enabled. This command output was produced by logging into the primary unit for virtual cluster 1 (hostname: 5001\_Slot\_4, serial number FG50012204400045).

The virtual clustering output shows that the cluster unit with host name 5001\_Slot\_4 and serial number FG50012204400045 is operating as the primary unit for virtual cluster 1 and the subordinate unit for virtual cluster 2.

For virtual cluster 1 the cluster unit that you have logged into is operating in the work state and the serial number of the primary unit for virtual cluster 1 is FG50012204400045. For virtual cluster 2 the cluster unit that you have logged into is operating in the standby state and the serial number of the primary unit for virtual cluster 2 is FG50012205400050.

```
Model: 5000
Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Master:128 5001_Slot_4      FG50012204400045 1
Slave :100 5001_Slot_3      FG50012205400050 0
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050
vcluster 2: standby 169.254.0.1
Slave :1 FG50012204400045
Master:0 FG50012205400050
```

The following example shows `get system ha status` output for the same cluster as shown in the previous example after using `execute ha manage 0` to log into the primary unit for virtual cluster 2 (hostname: 5001\_Slot\_3, serial number FG50012205400050).

```
Model: 5000
Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Slave :100 5001_Slot_3      FG50012205400050 0
Master:128 5001_Slot_4      FG50012204400045 1
number of vcluster: 2
vcluster 1: standby 169.254.0.2
Slave :1 FG50012205400050
Master:0 FG50012204400045
vcluster 2: work 169.254.0.1
Master:0 FG50012205400050
Slave :1 FG50012204400045
```

The following example shows `get system ha status` output for a virtual cluster configuration where the cluster unit with hostname: 5001\_Slot\_4 and serial number FG50012204400045 is the primary unit for both virtual clusters. This command output is produced by logging into cluster unit with host name 5001\_Slot\_4 and serial number FG50012204400045.

```
Model: 5000
```

```

Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Master:128 5001_Slot_4      FG50012204400045 1
Slave :100 5001_Slot_3      FG50012205400050 0
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050
vcluster 2: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050

```

## About the HA cluster index and the execute ha manage command

When a cluster starts up, the FortiGate Cluster Protocol (FGCP) assigns a cluster index and a HA heartbeat IP address to each cluster unit based on the serial number of the cluster unit. The FGCP selects the cluster unit with the highest serial number to become the primary unit. The FGCP assigns a cluster index of 0 and an HA heartbeat IP address of 169.254.0.1 to this unit. The FGCP assigns a cluster index of 1 and an HA heartbeat IP address of 169.254.0.2 to the cluster unit with the second highest serial number. If the cluster contains more units, the cluster unit with the third highest serial number is assigned a cluster index of 2 and an HA heartbeat IP address of 169.254.0.3, and so on. You can display the cluster index assigned to each cluster unit using the `get system ha status` command. Also when you use the `execute ha manage` command you select a cluster unit to log into by entering its cluster index.

The cluster index and HA heartbeat IP address only change if a unit leaves the cluster or if a new unit joins the cluster. When one of these events happens, the FGCP resets the cluster index and HA heartbeat IP address of each cluster unit according to serial number in the same way as when the cluster first starts up.

Each cluster unit keeps its assigned cluster index and HA heartbeat IP address even as the units take on different roles in the cluster. After the initial cluster index and HA heartbeat IP addresses are set according to serial number, the FGCP checks other primary unit selection criteria such as device priority and monitored interfaces. Checking these criteria could result in selecting a cluster unit without the highest serial number to operate as the primary unit.

Even if the cluster unit without the highest serial number now becomes the primary unit, the cluster indexes and HA heartbeat IP addresses assigned to the individual cluster units do not change. Instead the FGCP assigns a second cluster index, which could be called the operating cluster index, to reflect this role change. The operating cluster index is 0 for the primary unit and 1 and higher for the other units in the cluster. By default both sets of cluster indexes are the same. But if primary unit selection selects the cluster unit that does not have the highest serial number to be the primary unit then this cluster unit is assigned an operating cluster index of 0. The operating cluster index is used by the FGCP only. You can display the operating cluster index assigned to each cluster unit using the `get system ha status` command. There are no CLI commands that reference the operating cluster index.

Even though there are two cluster indexes there is only one HA heartbeat IP address and the HA heartbeat address is not affected by a change in the operating cluster index.

## Using the execute ha manage command

When you use the CLI command `execute ha manage <index_integer>` to connect to the CLI of another cluster unit, the `<index_integer>` that you enter is the cluster index of the unit that you want to connect to.

## Using get system ha status to display cluster indexes

You can display the cluster index assigned to each cluster unit using the CLI command `get system ha status`. The following example shows the information displayed by the `get system ha status` command for a cluster consisting of two FortiGate-5001SX units operating in active-passive HA mode with virtual domains not enabled and without virtual clustering.

```
get system ha status
Model: 5000
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
Slave :128 5001_slot_11 FG50012204400045 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG50012205400050
Slave :1 FG50012204400045
```

In this example, the cluster unit with serial number FG50012205400050 has the highest serial number and so has a cluster index of 0 and the cluster unit with serial number FG50012204400045 has a cluster index of 1. From the CLI of the primary (or master) unit of this cluster you can connect to the CLI of the subordinate (or slave) unit using the following command:

```
execute ha manage 1
```

This works because the cluster unit with serial number FG50012204400045 has a cluster index of 1.

The `get system ha status` command output shows two similar lists of indexes and serial numbers. The listing on the sixth and seventh lines of the command output are the cluster indexes assigned according to cluster unit serial number. These are the cluster indexes that you enter when using the `execute ha manage` command. The cluster indexes shown in the last two lines of the command output are the operating cluster indexes that reflect how the cluster units are actually operating in the cluster. In this example both sets of cluster indexes are the same.

The last three lines of the command output display the status of vcluster 1. In a cluster consisting of two cluster units operating without virtual domains enabled all clustering actually takes place in virtual cluster 1. HA is designed to work this way to support virtual clustering. If this cluster was operating with virtual domains enabled, adding virtual cluster 2 is similar to adding a new copy of virtual cluster 1. Virtual cluster 2 is visible in the `get system ha status` command output when you add virtual domains to virtual cluster 2.

The HA heartbeat IP address displayed on line 8 is the HA heartbeat IP address of the cluster unit that is actually operating as the primary unit. For a default configuration this IP address will always be 169.254.0.1 because the cluster unit with the highest serial number will be the primary unit. This IP address changes if the operating primary unit is not the primary unit with the highest serial number.

## Example: actual and operating cluster indexes do not match

This example shows the `get system ha status` command output for the same cluster of two FortiGate-5001SX units. However, in this example the device priority of the cluster unit with the serial number FG50012204400045 is increased to 200. As a result the cluster unit with the lowest serial number becomes the primary unit. This means the actual and operating cluster indexes of the cluster units do not match.

```
get system ha status
Model: 5000
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
Slave :200 5001_slot_11 FG50012204400045 1
number of vcluster: 1
vcluster 1: work 169.254.0.2
Master:1 FG50012205400050
Slave :0 FG50012204400045
```

The actual cluster indexes have not changed but the operating cluster indexes have. Also, the HA heartbeat IP address displayed for vcluster 1 has changed to 169.254.0.2.

## Virtual clustering example output

The `get system ha status` command output is the same if a cluster is operating with virtual clustering turned on but with all virtual domains in virtual cluster 1. The following `get system ha status` command output example shows the same cluster operating as a virtual cluster with virtual domains in virtual cluster 1 and added to virtual cluster 2. In this example the cluster unit with serial number FG50012204400045 is the primary unit for virtual cluster 1 and the cluster unit with serial number FG50012205400050 is the primary unit for virtual cluster 2.

```
get system ha status
Model: 5000
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
Slave :200 5001_slot_11 FG50012204400045 1
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master:1 FG50012205400050
Slave :0 FG50012204400045
vcluster 2: standby 169.254.0.1
Master:0 FG50012205400050
Slave :1 FG50012204400045
```

This example shows three sets of indexes. The indexes in lines six and seven are still used by the `execute ha manage` command. The indexes on lines ten and eleven are for the primary and subordinate units in virtual cluster 1 and the indexes on the last two lines are for virtual cluster 2.

## Managing individual cluster units

The following procedure describes how to use SSH to log into the primary unit CLI and from there to use the `execute ha manage` command to connect to the CLI of any other unit in the

cluster. The procedure is very similar if you use telnet, or the web-based manager dashboard CLI console.

You can use the `execute ha manage` command from the CLI of any cluster unit to log into the CLI of another the cluster unit. Usually you would use this command from the CLI of the primary unit to log into the CLI of a subordinate unit. However, if you have logged into a subordinate unit CLI, you can use this command to log into the primary unit CLI, or the CLI of another subordinate unit.

Using SSH or telnet or the web-based manager dashboard CLI console you can only log into the primary unit CLI. Using a direct console connection you can log into any cluster unit. In both cases you can use `execute ha manage` to connect to the CLI of other cluster units.

You log into the subordinate unit using the `FGT_ha_admin` administrator account. This built-in administrator account gives you read and write permission on the subordinate unit. Normally this built-in administrative account is not visible, however `FGT_ha_admin` does appear in event log messages.

---

1. Use SSH to connect to the cluster and log into the primary unit CLI.

Connect to any cluster interface configured for SSH administrative access to log into the cluster.

2. Enter the following command followed by a space and type a question mark (?):

```
execute ha manage
```

The CLI displays a list of all the subordinate units in the cluster. Each cluster unit is numbered, starting at 1. The information displayed for each cluster unit includes the unit serial number and the host name of the unit.

3. Complete the command with the number of the subordinate unit to log into. For example, to log into subordinate unit 1, enter the following command:

```
execute ha manage 1
```

Press Enter to connect to and log into the CLI of the selected subordinate unit. If this subordinate unit has a different host name, the CLI prompt changes to this host name.

You can use CLI commands to manage this subordinate unit. If you make changes to the configuration of any cluster unit (primary or subordinate unit) these changes are synchronized to all cluster units.

4. You can now use the `execute ha manage` command to connect to any other cluster unit (including the primary unit). You can also use the `exit` command to return to the primary unit CLI.

## Disconnecting a cluster unit from a cluster

Use the following procedures to disconnect a cluster unit from a functioning cluster without disrupting the operation of the cluster. You can disconnect a cluster unit if you need to use the disconnected FortiGate unit for another purpose, such as to act as a standalone firewall.

You can use the following procedures for a standard cluster and for a virtual clustering configuration. To use the following procedures from a virtual cluster you must be logged in as the admin administrator and you must have selected Global Configuration.

When you disconnect a cluster unit you must assign an IP address and netmask to one of the interfaces of the disconnected unit. You can disconnect any unit from the cluster even the primary unit. After the unit is disconnected, the cluster responds as if the disconnected unit has failed. The cluster may renegotiate and may select a new primary unit.

When the cluster unit is disconnected the HA mode is changed to standalone. In addition, all interface IP addresses of the disconnected unit are set to 0.0.0.0 except for the interface that you configure.

Otherwise the configuration of the disconnected unit is not changed. The HA configuration of the disconnected unit is not changed either (except to change the HA mode to Standalone).

#### To disconnect a cluster unit from a cluster - web-based manager

1. Go to *System > Config > HA* to view the cluster members list.
2. Select the Disconnect from cluster icon for the cluster unit to disconnect from the cluster.
3. Select the interface that you want to configure. You also specify the IP address and netmask for this interface. When the FortiGate unit is disconnected, all management access options are enabled for this interface.
4. Specify an IP address and netmask for the interface. You can use this IP address to connect to the interface to configure the disconnected FortiGate unit.
5. Select OK.

The FortiGate unit is disconnected from the cluster and the cluster may renegotiate and select a new primary unit. The selected interface of the disconnected unit is configured with the specified IP address and netmask.

#### To disconnect a cluster unit from a cluster - CLI

1. Enter the following command to disconnect a cluster unit with serial number FGT5002803033050. The internal interface of the disconnected unit is set to IP address 1.1.1.1 and netmask 255.255.255.0.

```
execute ha disconnect FGT5002803033050 internal 1.1.1.1 255.255.255.0
```

## Adding a disconnected FortiGate unit back to its cluster

If you disconnect a FortiGate unit from a cluster, you can re-connect the disconnected FortiGate unit to the cluster by setting the HA mode of the disconnected unit to match the HA mode of the cluster. Usually the disconnected unit rejoins the cluster as a subordinate unit and the cluster automatically synchronizes its configuration.

You do not have to change the HA password on the disconnected unit unless the HA password has been changed after the unit was disconnected. Disconnecting a unit from a cluster does not change the HA password.

You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. You should also make sure that the HA *override* CLI option is not enabled on the disconnected unit. Otherwise, when the disconnected unit joins the cluster, the cluster will renegotiate and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units. This configuration change might disrupt the operation of the cluster.

The following procedure assumes that the disconnected FortiGate unit is correctly physically connected to your network and to the cluster but is not running in HA mode and not part of the cluster.

Before you start this procedure you should note the device priority of the primary unit.

### To add a disconnected FortiGate unit back to its cluster - web-based manager

1. Log into the disconnected FortiGate unit.  
If virtual domains are enabled, log in as the admin administrator and select Global Configuration.
2. Go to *System > Config > HA*.
3. Change Mode to match the mode of the cluster.
4. If required, change the group name and password to match the cluster.
5. Set the Device Priority lower than the device priority of the primary unit.
6. Select OK.

The disconnected FortiGate unit joins the cluster.

### To add a disconnected FortiGate unit back to its cluster - CLI

1. Log into the CLI of the FortiGate unit to be added back to the cluster.
2. Enter the following command to access the global configuration and add the FortiGate unit back to a cluster operating in active-passive mode and set the device priority to 50 (a low number) so that this unit will not become the primary unit:

```
config global
    config system ha
        set mode a-p
        set priority 50
    end
end
```

You may have to also change the group name, group id and password. However if you have not changed these for the cluster or the FortiGate unit after it was disconnected from the cluster you should not have to adjust them now.

## HA diagnose commands

You can use the following diagnose command to display a data about a cluster:

```
diagnose sys ha dump-by {all-xdb | all-vcluster| rcache | all-group |
memory | debug-zone | vdom | kernel | device | stat| sesync}
```

The example out put below is from a cluster of two FortiGate-5001Cs. In this cluster the base1 and base2 interfaces communicate the HA heartbeat and port monitoring has been added to poort1.

## all-xdb

This command displays information about the current configuration of the cluster and how its operating. You can use the out to determine the primary unit, the state of port monitoring as well as most cluster configuration details and status.

```
diagnose sys ha dump-by all-xdb
    HA information.
idx=1,nxentry=2,linkfails=7,flags=0,digest=7.72.e3.2e.8e.d1...
xentry FG-5KC3E13800046 nhbdev=2,nventry=0, hops=0.
    base1, 50, mac=0.9.f,bc.e.6c, neighbor=1.

```

## stat

This command displays some statistics about how well the cluster is functioning. Information includes packet counts, memory use, failed links and ping failures.

```
diagnose sys ha dump-by stat
      HA information.
packet count = 1, memory = 220.
check_linkfails = 0, linkfails = 0, check_pingsvrfails = 2822
bufcnt = -5, bufmem = 0
```

# HA and failover protection

In FortiGate active-passive HA, the FortiGate Clustering Protocol (FGCP) provides failover protection. This means that an active-passive cluster can provide FortiGate services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiGate unit. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially in a mission-critical environment.

The FGCP supports three kinds of failover protection. Device failover automatically replaces a failed device and restarts traffic flow with minimal impact on the network. Link failover maintains traffic flow if a link fails. Session failover resumes communication sessions with minimal loss of data if a device or link failover occurs.

This chapter describes how FGCP failover protection works and provides detailed NAT/Route and Transparent mode packet flow descriptions.

This chapter contains the following sections:

- [About active-passive failover](#)
- [About active-active failover](#)
- [Device failover](#)
- [HA heartbeat and communication between cluster units](#)
- [Cluster virtual MAC addresses](#)
- [Synchronizing the configuration](#)
- [Synchronizing kernel routing tables](#)
- [Synchronizing IPsec VPN SAs](#)
- [Link failover \(port monitoring or interface monitoring\)](#)
- [Subsecond failover](#)
- [Remote link failover](#)
- [Session failover \(session pick-up\)](#)
- [WAN optimization and HA](#)
- [Failover and attached network equipment](#)
- [Monitoring cluster units for failover](#)
- [NAT/Route mode active-passive cluster packet flow](#)
- [Transparent mode active-passive cluster packet flow](#)
- [Failover performance](#)

## About active-passive failover

To achieve failover protection in an active-passive cluster, one of the cluster units functions as the primary unit, while the rest of the cluster units are subordinate units, operating in an active stand-by mode. The cluster IP addresses and HA virtual MAC addresses are associated with the cluster interfaces of the primary unit. All traffic directed at the cluster is actually sent to and processed by the primary unit.

While the cluster is functioning, the primary unit functions as the FortiGate network security device for the networks that it is connected to. In addition, the primary unit and subordinate

units use the HA heartbeat to keep in constant communication. The subordinate units report their status to the cluster unit and receive and store connection and state table updates.

## Device failure

If the primary unit encounters a problem that is severe enough to cause it to fail, the remaining cluster units negotiate to select a new primary unit. This occurs because all of the subordinate units are constantly waiting to negotiate to become primary units. Only the heartbeat packets sent by the primary unit keep the subordinate units from becoming primary units. Each received heartbeat packet resets negotiation timers in the subordinate units. If this timer is allowed to run out because the subordinate units do not receive heartbeat packets from the primary unit, the subordinate units assume that the primary unit has failed, and negotiate to become primary units themselves.

Using the same FGCP negotiation process that occurs when the cluster starts up, after they determine that the primary unit has failed, the subordinate units negotiate amongst themselves to select a new primary unit. The subordinate unit that wins the negotiation becomes the new primary unit with the same MAC and IP addresses as the former primary unit. The new primary unit then sends gratuitous ARP packets out all of its interfaces to inform attached switches to send traffic to the new primary unit. Sessions then resume with the new primary unit.

## Link failure

If a primary unit interface fails or is disconnected while a cluster is operation, a link failure occurs. When a link failure occurs the cluster units negotiate to select a new primary unit. Since the primary unit has not stopped operating, it participates in the negotiation. The link failure means that a new primary unit must be selected and the cluster unit with the link failure joins the cluster as a subordinate unit.

Just as for a device failover, the new primary unit sends gratuitous arp packets out all of its interfaces to inform attached switches to send traffic to it. Sessions then resume with the new primary unit.

If a subordinate unit experiences a device failure its status in the cluster does not change. However, in future negotiations a cluster unit with a link failure is unlikely to become the primary unit.

## Session failover

If you enable session failover (also called session pickup) for the cluster, during cluster operation the primary unit informs the subordinate units of changes to the primary unit connection and state tables, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster.

After a failover the new primary unit recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary unit and are handled according to their last known state.

If you leave session pickup disabled, the cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed.

## Primary unit recovery

If a primary unit recovers after a device or link failure, it will operate as a subordinate unit, unless the `override` CLI keyword is enabled and its device priority is set higher than the unit priority of other cluster units (see [“HA override” on page 1138](#)).

## About active-active failover

HA failover in a cluster running in active-active mode is similar to active-passive failover described above. Active-active subordinate units are constantly waiting to negotiate to become primary units and, if session failover is enabled, continuously receive connection state information from the primary unit. If the primary unit fails, or one of the primary unit interfaces fails, the cluster units use the same mechanisms to detect the failure and to negotiate to select a new primary unit. If session failover is enabled, the new primary unit also maintains communication sessions through the cluster using the shared connection state table.

Active-active HA load balances sessions among all cluster units. For session failover, the cluster must maintain all of these sessions. To load balance sessions, the functioning cluster uses a load balancing schedule to distribute sessions to all cluster units. The shared connection state table tracks the communication sessions being processed by all cluster units (not just the primary unit). After a failover, the new primary unit uses the load balancing schedule to re-distribute all of the communication sessions recorded in the shared connection state table among all of the remaining cluster units. The connections continue to be processed by the cluster, but possibly by a different cluster unit, and are handled according to their last known state.

## Device failover

The FGCP provides transparent device failover. Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

In the case of FortiOS HA, the device is the primary unit. If the primary unit fails, device failover ensures that one of the subordinate units in the cluster automatically takes the place of the primary unit and can continue processing network traffic in the same way as the failed primary unit.

Device failover does not maintain communication sessions. After a device failover, communication sessions have to be restarted. To maintain communication sessions, you must enable session failover. See [“Session failover \(session pick-up\)” on page 1330](#).

---

FortiGate HA device failover is supported by the HA heartbeat, virtual MAC addresses, configuration synchronization, route synchronization and IPsec VPN SA synchronization.

The HA heartbeat makes sure that the subordinate units detect a primary unit failure. If the primary unit fails to respond on time to HA heartbeat packets the subordinate units assume that the primary unit has failed and negotiate to select a new primary unit.

The new primary unit takes the place of the failed primary unit and continues functioning in the same way as the failed primary unit. For the new primary unit to continue functioning like the failed primary unit, the new primary unit must be able to reconnect to network devices and the new primary unit must have the same configuration as the failed primary unit.

FortiGate HA uses virtual MAC addresses to reconnect the new primary unit to network devices. The FGCP causes the new primary unit interfaces to acquire the same virtual MAC addresses as the failed primary unit. As a result, the new primary unit has the same network identity as the failed primary unit.

The new primary unit interfaces have different physical connections than the failed primary unit. Both the failed and the new primary unit interfaces are connected to the same switches, but the new primary unit interfaces are connected to different ports on these switches. To make sure

that the switches send packets to the new primary unit, the new primary unit interfaces send gratuitous ARP packets to the connected switches. These gratuitous ARP packets notify the switches that the primary unit MAC and IP addresses are on different switch ports and cause the switches to send packets to the ports connected to the new primary unit. In this way, the new primary unit continues to receive packets that would otherwise have been sent to the failed primary unit.

Configuration synchronization means that the new primary unit always has the same configuration as the failed primary unit. As a result the new primary unit operates in exactly the same way as the failed primary unit. If configuration synchronization were not available the new primary unit may not process network traffic in the same way as the failed primary unit.

Route synchronization synchronizes the primary unit routing table to all subordinate units so that after a failover the new primary unit does not have to form a completely new routing table. IPsec VPN SA synchronization synchronizes IPsec VPN security associations (SAs) and other IPsec session data so that after a failover the new primary unit can resume IPsec tunnels without having to establish new SAs.

## HA heartbeat and communication between cluster units

The HA heartbeat keeps cluster units communicating with each other. The heartbeat consists of hello packets that are sent at regular intervals by the heartbeat interface of all cluster units. These hello packets describe the state of the cluster unit and are used by other cluster units to keep all cluster units synchronized.

HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8892. The default time interval between HA heartbeats is 200 ms. The FGCP uses link-local IP4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

For best results, isolate the heartbeat devices from your user networks by connecting the heartbeat devices to a separate switch that is not connected to any network. If the cluster consists of two FortiGate units you can connect the heartbeat device interfaces directly using a crossover cable. Heartbeat packets contain sensitive information about the cluster configuration. Heartbeat packets may also use a considerable amount of network bandwidth. For these reasons, it is preferable to isolate heartbeat packets from your user networks.

On startup, a FortiGate unit configured for HA operation broadcasts HA heartbeat hello packets from its HA heartbeat interface to find other FortiGate units configured to operate in HA mode. If two or more FortiGate units operating in HA mode connect with each other, they compare HA configurations (HA mode, HA password, and HA group ID). If the HA configurations match, the units negotiate to form a cluster.

While the cluster is operating, the HA heartbeat confirms that all cluster units are functioning normally. The heartbeat also reports the state of all cluster units, including the communication sessions that they are processing.

### Heartbeat interfaces

A heartbeat interface is an Ethernet network interface in a cluster that is used by the FGCP for HA heartbeat communications between cluster units.

To change the HA heartbeat configuration go to *System > Config > HA* and select the *FortiGate interfaces to use as HA heartbeat interfaces*.

Do not use a switch port for the HA heartbeat traffic. This configuration is not supported.

---

From the CLI enter the following command to make port4 and port5 HA heartbeat interfaces and give both interfaces a heartbeat priority of 150:

```
config system ha
    set hbdev port4 150 port5 150
end
```

The following example shows how to change the default heartbeat interface configuration so that the port4 and port1 interfaces can be used for HA heartbeat communication and to give the port4 interface the highest heartbeat priority so that port4 is the preferred HA heartbeat interface.

```
config system ha
    set hbdev port4 100 port1 50
end
```

By default, for most FortiGate models two interfaces are configured to be heartbeat interfaces. You can change the heartbeat interface configuration as required. For example you can select additional or different heartbeat interfaces. You can also select only one heartbeat interface.

In addition to selecting the heartbeat interfaces, you also set the *Priority* for each heartbeat interface. In all cases, the heartbeat interface with the highest priority is used for all HA heartbeat communication. If the interface fails or becomes disconnected, the selected heartbeat interface that has the next highest priority handles all heartbeat communication.

If more than one heartbeat interface has the same priority, the heartbeat interface with the highest priority that is also highest in the heartbeat interface list is used for all HA heartbeat communication. If this interface fails or becomes disconnected, the selected heartbeat interface with the highest priority that is next highest in the list handles all heartbeat communication.

The default heartbeat interface configuration sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration if one or both of the default heartbeat interfaces are connected. You can select different heartbeat interfaces, select more heartbeat interfaces and change heartbeat priorities according to your requirements.

For the HA cluster to function correctly, you must select at least one heartbeat interface and this interface of all of the cluster units must be connected together. If heartbeat communication is interrupted and cannot failover to a second heartbeat interface, the cluster units will not be able to communicate with each other and more than one cluster unit may become a primary unit. As a result the cluster stops functioning normally because multiple devices on the network may be operating as primary units with the same IP and MAC addresses creating a kind of split brain scenario.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0. The higher the number the higher the priority.

In most cases you can maintain the default heartbeat interface configuration as long as you can connect the heartbeat interfaces together. Configuring HA heartbeat interfaces is the same for virtual clustering and for standard HA clustering.

You can enable heartbeat communications for physical interfaces, but not for VLAN subinterfaces, IPsec VPN interfaces, redundant interfaces, or for 802.3ad aggregate interfaces. You cannot select these types of interfaces in the heartbeat interface list.

Selecting more heartbeat interfaces increases reliability. If a heartbeat interface fails or is disconnected, the HA heartbeat fails over to the next heartbeat interface.

You can select up to 8 heartbeat interfaces. This limit only applies to FortiGate units with more than 8 physical interfaces.

HA heartbeat traffic can use a considerable amount of network bandwidth. If possible, enable HA heartbeat traffic on interfaces used only for HA heartbeat traffic or on interfaces connected to less busy networks.

## Connecting HA heartbeat interfaces

For most FortiGate models if you do not change the heartbeat interface configuration, you can isolate the default heartbeat interfaces of all of the cluster units by connecting them all to the same switch. Use one switch per heartbeat interface. If the cluster consists of two units you can connect the heartbeat interfaces together using crossover cables. For an example of how to connect heartbeat interfaces, see [“Connecting a FortiGate HA cluster” on page 1127](#).

HA heartbeat and data traffic are supported on the same cluster interface. In NAT/Route mode, if you decide to use heartbeat interfaces for processing network traffic or for a management connection, you can assign the interface any IP address. This IP address does not affect HA heartbeat traffic.

In Transparent mode, you can connect the heartbeat interface to your network and enable management access. You would then establish a management connection to the interface using the Transparent mode management IP address. This configuration does not affect HA heartbeat traffic.

## Heartbeat packets and heartbeat interface selection

HA heartbeat hello packets are constantly sent by all of the enabled heartbeat interfaces. Using these hello packets, each cluster unit confirms that the other cluster units are still operating. The FGCP selects one of the heartbeat interfaces to be used for communication between the cluster units. The FGCP selects the heartbeat interface for heartbeat communication based on the linkfail states of the heartbeat interfaces, on the priority of the heartbeat interfaces, and on the interface index.

The FGCP checks the linkfail state of all heartbeat interfaces to determine which ones are connected. The FGCP selects one of these connected heartbeat interfaces to be the one used for heartbeat communication. The FGCP selects the connected heartbeat interface with the highest priority for heartbeat communication.

If more than one connected heartbeat interface has the highest priority the FGCP selects the heartbeat interface with the lowest interface index. The web-based manager lists the FortiGate unit interfaces in alphabetical order. This order corresponds to the interface index order with lowest index at the top and highest at the bottom. If more than one heartbeat interface has the highest priority, the FGCP selects the interface that is highest in the heartbeat interface list (or first in alphabetical order) for heartbeat communication.

If the interface that is processing heartbeat traffic fails or becomes disconnected, the FGCP uses the same criteria to select another heartbeat interface for heartbeat communication. If the original heartbeat interface is fixed or reconnected, the FGCP again selects this interface for heartbeat communication.

The HA heartbeat communicates cluster session information, synchronizes the cluster configuration, synchronizes the cluster routing table, and reports individual cluster member status. The HA heartbeat constantly communicates HA status information to make sure that the cluster is operating properly.

## Interface index and display order

The web-based manager and CLI display interface names in alphanumeric order. For example, the sort order for a FortiGate unit with 10 interfaces (named port1 through port10) places port10 at the bottom of the list:

- port1
- port2 through 9
- port10

However, interfaces are indexed in hash map order, rather than purely by alphabetic order or purely by interface number value comparisons. As a result, the list is sorted primarily alphabetical by interface name (for example, base1 is before port1), then secondarily by index numbers:

- port1
- port10
- port2 through port9

## HA heartbeat interface IP addresses

The FGCP uses link-local IP4 addresses ([RFC 3927](#)) in the 169.254.0.x range for HA heartbeat interface IP addresses and for inter-VDOM link interface IP addresses. When a cluster initially starts up, the primary unit heartbeat interface IP address is 169.254.0.1. Subordinate units are assigned heartbeat interface IP addresses in the range 169.254.0.2 to 169.254.0.63. HA inter-VDOM link interfaces on the primary unit are assigned IP addresses 169.254.0.65 and 169.254.0.66.

The ninth line of the following CLI command output shows the HA heartbeat interface IP address of the primary unit.

```
get system ha status
  Model: 620
  Mode: a-p
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:150 head_office_upper FG600B3908600825 1
  Slave :150 head_office_lower FG600B3908600705 0
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

You can also use the `execute traceroute` command from the subordinate unit CLI to display HA heartbeat IP addresses and the HA inter-VDOM link IP addresses. For example, use `execute ha manage 1` to connect to the subordinate unit CLI and then enter the following command to trace the route to an IP address on your network:

```
execute traceroute 172.20.20.10
  traceroute to 172.20.20.10 (172.20.20.10), 32 hops max, 72 byte packets
  1  169.254.0.1  0 ms  0 ms  0 ms
  2  169.254.0.66  0 ms  0 ms  0 ms
  3  172.20.20.10  0 ms  0 ms  0 ms
```

Both HA heartbeat and data traffic are supported on the same FortiGate interface. All heartbeat communication takes place on a separate VDOM called `vsys_ha`. Heartbeat traffic uses a virtual interface called `port_ha` in the `vsys_ha` VDOM. Data and heartbeat traffic use the same physical interface, but they're logically separated into separate VDOMs.

## Heartbeat packet Ethertypes

Normal IP packets are 802.3 packets that have an Ethernet type (Ethertype) field value of 0x0800. Ether type values other than 0x0800 are understood as level2 frames rather than IP packets.

By default, HA heartbeat packets use the following Ethertypes:

- HA heartbeat packets for NAT/Route mode clusters use Ether type 0x8890. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ether type of these packets using the `ha-eth-type` option of the `config system ha` command.
- HA heartbeat packets for Transparent mode clusters use Ether type 0x8891. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ether type of these packets using the `hc-eth-type` option of the `config system ha` command.
- HA telnet sessions between cluster units over HA heartbeat links use Ether type 0x8893. The telnet sessions are used to synchronize the cluster configurations. Telnet sessions are also used when an administrator uses the `execute ha manage` command to connect from one cluster unit CLI to another. You can change the Ether type of these packets using the `l2ep-eth-type` option of the `config system ha` command.

Because heartbeat packets are recognized as level2 frames, the switches and routers on your heartbeat network that connect to heartbeat interfaces must be configured to allow them. If level2 frames are dropped by these network devices, heartbeat traffic will not be allowed between the cluster units.

Some third-party network equipment may use packets with these Ethertypes for other purposes. For example, Cisco N5K/Nexus switches use Ether type 0x8890 for some functions. When one of these switches receives Ether type 0x8890 packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGate units connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8893, and 0x8891 to pass.

Alternatively, you can use the following CLI options to change the Ethertypes of the HA heartbeat packets:

```
config system ha
    set ha-eth-type <ha_ethertype_4-digit_hex>
    set hc-eth-type <hc_ethertype_4-digit_hex>
    set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For example, use the following command to change the Ethertype of the HA heartbeat packets from 0x8890 to 0x8895 and to change the Ethertype of HA Telnet session packets from 0x8891 to 0x889f:

```
config system ha
    set ha-eth-type 8895
    set l2ep-eth-type 889f
end
```

## Modifying heartbeat timing

In an HA cluster, if a cluster unit CPU becomes very busy, the cluster unit may not be able to send heartbeat packets on time. If heartbeat packets are not sent on time other units in the cluster may think that the cluster unit has failed and the cluster will experience a failover.

A cluster unit CPU may become very busy if the cluster is subject to a syn flood attack, if network traffic is very heavy, or for other similar reasons. You can use the following CLI commands to configure how the cluster times HA heartbeat packets:

```
config system ha
    set hb-interval <interval_integer>
    set hb-lost-threshold <threshold_integer>
    set helo-holddown <holddown_integer>
end
```

## Changing the lost heartbeat threshold

The lost heartbeat threshold is the number of consecutive heartbeat packets that are not received from another cluster unit before assuming that the cluster unit has failed. The default value is 6, meaning that if the 6 heartbeat packets are not received from a cluster unit then that cluster unit is considered to have failed. The range is 1 to 60 packets.

If the primary unit does not receive a heartbeat packet from a subordinate unit before the heartbeat threshold expires, the primary unit assumes that the subordinate unit has failed.

If a subordinate unit does not receive a heartbeat packet from the primary unit before the heartbeat threshold expires, the subordinate unit assumes that the primary unit has failed. The subordinate unit then begins negotiating to become the new primary unit.

The lower the `hb-lost-threshold` the faster a cluster responds when a unit fails. However, sometimes heartbeat packets may not be sent because a cluster unit is very busy. This can lead to a false positive failure detection. To reduce these false positives you can increase the `hb-lost-threshold`.

Use the following CLI command to increase the lost heartbeat threshold to 12:

```
config system ha
    set hb-lost-threshold 12
end
```

## Changing the heartbeat interval

The heartbeat interval is the time between sending HA heartbeat packets. The heartbeat interval range is 1 to 20 (100\*ms). The heartbeat interval default is 2 (200 ms).

A heartbeat interval of 2 means the time between heartbeat packets is 200 ms. Changing the heartbeat interval to 5 changes the time between heartbeat packets to 500 ms (5 \* 100ms = 500ms).

The HA heartbeat packets consume more bandwidth if the heartbeat interval is short. But if the heartbeat interval is very long, the cluster is not as sensitive to topology and other network changes.

Use the following CLI command to increase the heartbeat interval to 10:

```
config system ha
    set hb-interval 10
end
```

The heartbeat interval combines with the lost heartbeat threshold to set how long a cluster unit waits before assuming that another cluster unit has failed and is no longer sending heartbeat packets. By default, if a cluster unit does not receive a heartbeat packet from a cluster unit for  $6 * 200 = 1200$  milliseconds or 1.2 seconds the cluster unit assumes that the other cluster unit has failed.

You can increase both the heartbeat interval and the lost heartbeat threshold to reduce false positives. For example, increasing the heartbeat interval to 20 and the lost heartbeat threshold to 30 means a failure will be assumed if no heartbeat packets are received after  $30 * 2000$  milliseconds = 60,000 milliseconds, or 60 seconds.

Use the following CLI command to increase the heartbeat interval to 20 and the lost heartbeat threshold to 30:

```
config system ha
    set hb-lost-threshold 20
    set hb-interval 30
end
```

## Changing the time to wait in the hello state

The hello state hold-down time is the number of seconds that a cluster unit waits before changing from hello state to work state. After a failure or when starting up, cluster units operate in the hello state to send and receive heartbeat packets so that all the cluster units can find each other and form a cluster. A cluster unit should change from the hello state to work state after it finds all of the other FortiGate units to form a cluster with. If for some reason all cluster units cannot find each other during the hello state then some cluster units may be joining the cluster after it has formed. This can cause disruptions to the cluster and affect how it operates.

One reason for a delay in all of the cluster units joining the cluster could be the cluster units are located at different sites or if for some other reason communication is delayed between the heartbeat interfaces.

If cluster units are joining your cluster after it has started up or if it takes a while for units to join the cluster you can increase the time that the cluster units wait in the hello state. The hello state hold-down time range is 5 to 300 seconds. The hello state hold-down time default is 20 seconds.

Use the following CLI command to increase the time to wait in the hello state to 1 minute (60 seconds):

```
config system ha
    set hello-holddown 60
end
```

## Enabling or disabling HA heartbeat encryption and authentication

You can enable HA heartbeat encryption and authentication to encrypt and authenticate HA heartbeat packets. HA heartbeat packets should be encrypted and authenticated if the cluster interfaces that send HA heartbeat packets are also connected to your networks.

If HA heartbeat packets are not encrypted the cluster password and changes to the cluster configuration could be exposed and an attacker may be able to sniff HA packets to get cluster information. Enabling HA heartbeat message authentication prevents an attacker from creating false HA heartbeat messages. False HA heartbeat messages could affect the stability of the cluster.

HA heartbeat encryption and authentication are disabled by default. Enabling HA encryption and authentication could reduce cluster performance. Use the following CLI command to enable HA heartbeat encryption and authentication.

```
config system ha
    set authentication enable
    set encryption enable
end
```

HA authentication and encryption uses AES-128 for encryption and SHA1 for authentication.

## Cluster virtual MAC addresses

When a cluster is operating, the FGCP assigns virtual MAC addresses to each primary unit interface. HA uses virtual MAC addresses so that if a failover occurs, the new primary unit interfaces will have the same virtual MAC addresses and IP addresses as the failed primary unit. As a result, most network equipment would identify the new primary unit as the exact same device as the failed primary unit.

If the MAC addresses changed after a failover, the network would take longer to recover because all attached network devices would have to learn the new MAC addresses before they could communicate with the cluster.

If a cluster is operating in NAT/Route mode, the FGCP assigns a different virtual MAC address to each primary unit interface. VLAN subinterfaces are assigned the same virtual MAC address as the physical interface that the VLAN subinterface is added to. Redundant interfaces or 802.3ad aggregate interfaces are assigned the virtual MAC address of the first interface in the redundant or aggregate list.

If a cluster is operating in Transparent mode, the FGCP assigns a virtual MAC address for the primary unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

A MAC address conflict can occur if two clusters are operating on the same network. See [“Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain” on page 1305](#) for more information.

Subordinate unit MAC addresses do not change. You can verify this by connecting to the subordinate unit CLI and using the `get hardware interface nic` command to display the MAC addresses of each FortiGate interface.

---

When the new primary unit is selected after a failover, the primary unit sends gratuitous ARP packets to update the devices connected to the cluster interfaces (usually layer-2 switches) with the virtual MAC address. Gratuitous ARP packets configure connected network devices to associate the cluster virtual MAC addresses and cluster IP address with primary unit physical interfaces and with the layer-2 switch physical interfaces. This is sometimes called using gratuitous ARP packets (sometimes called GARP packets) to train the network. The gratuitous

ARP packets sent from the primary unit are intended to make sure that the layer-2 switch forwarding databases (FDBs) are updated as quickly as possible.

Sending gratuitous ARP packets is not required for routers and hosts on the network because the new primary unit will have the same MAC and IP addresses as the failed primary unit. However, since the new primary unit interfaces are connected to different switch interfaces than the failed primary unit, many network switches will update their FDBs more quickly after a failover if the new primary unit sends gratuitous ARP packets.

## Changing how the primary unit sends gratuitous ARP packets after a failover

When a failover occurs it is important that the devices connected to the primary unit update their FDBs as quickly as possible to reestablish traffic forwarding.

Depending on your network configuration, you may be able to change the number of gratuitous ARP packets and the time interval between ARP packets to reduce the cluster failover time.

You cannot disable sending gratuitous ARP packets, but you can use the following command to change the number of packets that are sent. For example, enter the following command to send 20 gratuitous ARP packets:

```
config system ha
    set arps 20
end
```

You can use this command to configure the primary unit to send from 1 to 60 ARP packets. Usually you would not change the default setting of 5. In some cases, however, you might want to reduce the number of gratuitous ARP packets. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending a higher number gratuitous ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully, you could reduce the number of gratuitous ARP packets that are sent to reduce the amount of traffic produced after a failover.

If failover is taking longer than expected, you may be able to reduce the failover time by increasing the number of gratuitous ARP packets sent.

You can also use the following command to change the time interval in seconds between gratuitous ARP packets. For example, enter the following command to change the time between ARP packets to 3 seconds:

```
config system ha
    set arps-interval 3
end
```

The time interval can be in the range of 1 to 20 seconds. The default is 8 seconds between gratuitous ARP packets. Normally you would not need to change the time interval. However, you could decrease the time to be able to send more packets in less time if your cluster takes a long time to failover.

There may also be a number of reasons to set the interval higher. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending gratuitous ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully you could increase the interval to reduce the amount of traffic produced after a failover.

For more information about gratuitous ARP packets see [RFC 826](#) and [RFC 3927](#).

## Disabling gratuitous ARP packets after a failover

You can use the following command to turn off sending gratuitous ARP packets after a failover:

```
config system ha
    set gratuitous-arps disable
end
```

Sending gratuitous ARP packets is turned on by default.

In most cases you would want to send gratuitous ARP packets because its a reliable way for the cluster to notify the network to send traffic to the new primary unit. However, in some cases, sending gratuitous ARP packets may be less optimal. For example, if you have a cluster of FortiGate units in Transparent mode, after a failover the new primary unit will send gratuitous ARP packets to all of the addresses in its Forwarding Database (FDB). If the FDB has a large number of addresses it may take extra time to send all the packets and the sudden burst of traffic could disrupt the network.

If you choose to disable sending gratuitous ARP packets you must first enable the `link-failed-signal` setting. The cluster must have some way of informing attached network devices that a failover has occurred.

For more information about the `link-failed-signal` setting, see [“Updating MAC forwarding tables when a link failover occurs” on page 1323](#).

## How the virtual MAC address is determined

The virtual MAC address is determined based on following formula:

```
00-09-0f-09-<group-id_hex>-<vcluster_integer><idx>
```

where

`<group-id_hex>` is the HA Group ID for the cluster converted to hexadecimal. [Table 58](#) lists the virtual MAC address set for each group ID.

**Table 58:** HA group ID in integer and hexadecimal format

Integer Group ID	Hexadecimal Group ID
0	00
1	01
2	02
3	03
4	04
...	...
10	0a
11	0b
...	...
63	3f

**Table 58:** HA group ID in integer and hexadecimal format

...	...
255	ff

`<vcluster_integer>` is 0 for virtual cluster 1 and 2 for virtual cluster 2. If virtual domains are not enabled, HA sets the virtual cluster to 1 and by default all interfaces are in the root virtual domain. Including virtual cluster and virtual domain factors in the virtual MAC address formula means that the same formula can be used whether or not virtual domains and virtual clustering is enabled.

`<idx>` is the index number of the interface. Interfaces are numbered from 0 to x (where x is the number of interfaces). Interfaces are numbered according to their has map order. See [“Interface index and display order” on page 1296](#). The first interface has an index of 0. The second interface in the list has an index of 1 and so on.

Only the `<idx>` part of the virtual MAC address is different for each interface. The `<vcluster_integer>` would be different for different interfaces if multiple VDOMs have been added.

Between FortiOS releases interface indexing may change so the virtual MAC addresses assigned to individual FortiGate interfaces may also change.

### Example virtual MAC addresses

An HA cluster with HA group ID unchanged (default=0) and virtual domains not enabled would have the following virtual MAC addresses for interfaces port1 to port12:

- port1 virtual MAC: 00-09-0f-09-00-00
- port10 virtual MAC: 00-09-0f-09-00-01
- port2 virtual MAC: 00-09-0f-09-00-02
- port3 virtual MAC: 00-09-0f-09-00-03
- port4 virtual MAC: 00-09-0f-09-00-04
- port5 virtual MAC: 00-09-0f-09-00-05
- port6 virtual MAC: 00-09-0f-09-00-06
- port7 virtual MAC: 00-09-0f-09-00-07
- port8 virtual MAC: 00-09-0f-09-00-08
- port9 virtual MAC: 00-09-0f-09-00-09
- port11 virtual MAC: 00-09-0f-09-00-0a
- port12 virtual MAC: 00-09-0f-09-00-0b

If the group ID is changed to 34 these virtual MAC addresses change to:

- port1 virtual MAC: 00-09-0f-09-22-00
- port10 virtual MAC: 00-09-0f-09-22-01
- port2 virtual MAC: 00-09-0f-09-22-02
- port3 virtual MAC: 00-09-0f-09-22-03
- port4 virtual MAC: 00-09-0f-09-22-04
- port5 virtual MAC: 00-09-0f-09-22-05
- port6 virtual MAC: 00-09-0f-09-22-06
- port7 virtual MAC: 00-09-0f-09-22-07
- port8 virtual MAC: 00-09-0f-09-22-08
- port9 virtual MAC: 00-09-0f-09-22-09
- port11 virtual MAC: 00-09-0f-09-22-0a
- port12 virtual MAC: 00-09-0f-09-22-0b

A cluster with virtual domains enabled where the HA group ID has been changed to 23, port5 and port 6 are in the root virtual domain (which is in virtual cluster1), and port7 and port8 are in the vdom\_1 virtual domain (which is in virtual cluster 2) would have the following virtual MAC addresses:

port5 interface virtual MAC: 00-09-0f-09-23-05

port6 interface virtual MAC: 00-09-0f-09-23-06

port7 interface virtual MAC: 00-09-0f-09-23-27

port8 interface virtual MAC: 00-09-0f-09-23-28

## Displaying the virtual MAC address

Every FortiGate unit physical interface has two MAC addresses: the current hardware address and the permanent hardware address. The permanent hardware address cannot be changed, it is the actual MAC address of the interface hardware. The current hardware address can be changed. The current hardware address is the address seen by the network. For a FortiGate unit not operating in HA, you can use the following command to change the current hardware address of the port1 interface:

```
config system interface
    edit port1
        set macaddr <mac_address>
    end
end
```

For an operating cluster, the current hardware address of each cluster unit interface is changed to the HA virtual MAC address by the FGCP. The `macaddr` option is not available for a functioning cluster. You cannot change an interface MAC address and you cannot view MAC addresses from the `system interface` CLI command.

You can use the `get hardware nic <interface_name_str>` command to display both MAC addresses for any FortiGate interface. This command displays hardware information for the specified interface. Depending on their hardware configuration, this command may display different information for different interfaces. You can use this command to display the current hardware address as `Current_HWaddr` and the permanent hardware address as `Permanent_HWaddr`. For some interfaces the current hardware address is displayed as `MAC`.

The command displays a great deal of information about the interface so you may have to scroll the output to find the hardware addresses.

You can also use the `diagnose hardware deviceinfo nic <interface_str>` command to display both MAC addresses for any FortiGate interface.

Before HA configuration the current and permanent hardware addresses are the same. For example for one of the units in Cluster\_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 02:09:0f:78:18:c9
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

During HA operation the current hardware address becomes the HA virtual MAC address, for example for the units in Cluster\_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

The following command output for Cluster\_2 shows the same current hardware address for port1 as for the internal interface of Cluster\_2, indicating a MAC address conflict.

```
FG300A2904500238 # get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 00:09:0F:85:40:FD
.
.
.
```

## Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain

A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the

broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID.

This section describes a topology that can result in packet loss, how to determine if packets are being lost, and how to correct the problem by changing the HA Group ID.

Packet loss on a network can also be caused by IP address conflicts. Finding and fixing IP address conflicts can be difficult. However, if you are experiencing packet loss and your network contains two FortiGate HA clusters you can use the information in this article to eliminate one possible source of packet loss.

### Changing the HA group ID to avoid MAC address conflicts

Change the Group ID to change the virtual MAC address of all cluster interfaces. You can change the Group ID from the FortiGate CLI using the following command:

```
config system ha
    set group-id <id_integer>
end
```

### Example topology

The topology below shows two clusters. The Cluster\_1 internal interfaces and the Cluster\_2 port 1 interfaces are both connected to the same broadcast domain. In this topology the broadcast domain could be an internal network. Both clusters could also be connected to the Internet or to different networks.

**Figure 209:**Example HA topology with possible MAC address conflicts

### Ping testing for packet loss

If the network is experiencing packet loss, it is possible that you will not notice a problem unless you are constantly pinging both HA clusters. During normal operation of the network you also might not notice packet loss because the loss rate may not be severe enough to timeout TCP sessions. Also many common types of TCP traffic, such as web browsing, may not be greatly affected by packet loss. However, packet loss can have a significant effect on real time protocols that deliver audio and video data.

To test for packet loss you can set up two constant ping sessions, one to each cluster. If packet loss is occurring the two ping sessions should show alternating replies and timeouts from each cluster.

Cluster_1	Cluster_2
reply	timeout
reply	timeout
reply	timeout
timeout	reply
timeout	reply
reply	timeout
reply	timeout
timeout	reply
timeout	reply
timeout	reply
timeout	reply

### Viewing MAC address conflicts on attached switches

If two HA clusters with the same virtual MAC address are connected to the same broadcast domain (L2 switch or hub), the MAC address will conflict and bounce between the two clusters. This example Cisco switch MAC address table shows the MAC address flapping between different interfaces (1/0/1 and 1/0/4).

1	0009.0f09.0002	DYNAMIC	Gi1/0/1
1	0009.0f09.0002	DYNAMIC	Gi1/0/4

## Synchronizing the configuration

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit.

### Configuration settings that are not synchronized

The following settings are not synchronized among cluster units:

- HA override.
- HA device priority.
- The virtual cluster priority.
- The FortiGate unit host name.
- The HA priority setting for a ping server (or dead gateway detection) configuration.
- The system interface settings of the HA reserved management interface.
- The HA default route for the reserved management interface, set using the `ha-mgt-interface-gateway` option of the `config system ha` command.

The primary unit synchronizes all other configuration settings, including the other HA configuration settings.

## Disabling automatic configuration synchronization

In some cases you may want to use the following command to disable automatic synchronization of the primary unit configuration to all cluster units.

```
config system ha
    set sync-config disable
end
```

When this option is disabled the cluster no longer synchronizes configuration changes. If a device failure occurs, the new primary unit may not have the same configuration as the failed primary unit. As a result, the new primary unit may process sessions differently or may not function on the network in the same way.

In most cases you should not disable automatic configuration synchronization. However, if you have disabled this feature you can use the `execute ha synchronize` command to manually synchronize a subordinate unit's configuration to that of the primary unit.

You must enter `execute ha synchronize` commands from the subordinate unit that you want to synchronize with the primary unit. Use the `execute ha manage` command to access a subordinate unit CLI. See [“Viewing cluster status from the CLI” on page 1277](#).

For example, to access the first subordinate unit and force a synchronization at any time, even if automatic synchronization is disabled enter:

```
execute ha manage 0
execute ha synchronize start
```

You can use the following command to stop a synchronization that is in progress.

```
execute ha synchronize stop
```

You can use the following command to a synchronization all parts of the configuration:

```
execute ha synchronize all
```

Individual options are also available to synchronize parts of the configuration. For example, enter the following command to synchronize CA certificates:

```
execute ha synchronize ca
```

## Incremental synchronization

When you log into the cluster web-based manager or CLI to make configuration changes, you are actually logging into the primary unit. All of your configuration changes are first made to the primary unit. Incremental synchronization then immediately synchronizes these changes to all of the subordinate units.

When you log into a subordinate unit CLI (for example using `execute ha manage`) all of the configuration changes that you make to the subordinate unit are also immediately synchronized to all cluster units, including the primary unit, using the same process.

Incremental synchronization also synchronizes other dynamic configuration information such as the DHCP server address lease database, routing table updates, IPsec SAs, MAC address tables, and so on. See [“FortiGate HA compatibility with PPPoE and DHCP” on page 1142](#) for more information about DHCP server address lease synchronization and [“Synchronizing kernel routing tables” on page 1315](#) for information about routing table updates.

Whenever a change is made to a cluster unit configuration, incremental synchronization sends the same configuration change to all other cluster units over the HA heartbeat link. An HA

synchronization process running on the each cluster unit receives the configuration change and applies it to the cluster unit. The HA synchronization process makes the configuration change by entering a CLI command that appears to be entered by the administrator who made the configuration change in the first place.

Synchronization takes place silently, and no log messages are recorded about the synchronization activity. However, log messages can be recorded by the cluster units when the synchronization process enters CLI commands. You can see these log messages on the subordinate units if you enable event logging and set the minimum severity level to *Information* and then check the event log messages written by the cluster units when you make a configuration change.

You can also see these log messages on the primary unit if you make configuration changes from a subordinate unit.

## Periodic synchronization

Incremental synchronization makes sure that as an administrator makes configuration changes, the configurations of all cluster units remain the same. However, a number of factors could cause one or more cluster units to go out of sync with the primary unit. For example, if you add a new unit to a functioning cluster, the configuration of this new unit will not match the configuration of the other cluster units. Its not practical to use incremental synchronization to change the configuration of the new unit.

Periodic synchronization is a mechanism that looks for synchronization problems and fixes them. Every minute the cluster compares the configuration file checksum of the primary unit with the configuration file checksums of each of the subordinate units. If all subordinate unit checksums are the same as the primary unit checksum, all cluster units are considered synchronized.

If one or more of the subordinate unit checksums is not the same as the primary unit checksum, the subordinate unit configuration is considered out of sync with the primary unit. The checksum of the out of sync subordinate unit is checked again every 15 seconds. This re-checking occurs in case the configurations are out of sync because an incremental configuration sequence has not completed. If the checksums do not match after 5 checks the subordinate unit that is out of sync retrieves the configuration from the primary unit. The subordinate unit then reloads its configuration and resumes operating as a subordinate unit with the same configuration as the primary unit.

The configuration of the subordinate unit is reset in this way because when a subordinate unit configuration gets out of sync with the primary unit configuration there is no efficient way to determine what the configuration differences are and to correct them. Resetting the subordinate unit configuration becomes the most efficient way to resynchronize the subordinate unit.

Synchronization requires that all cluster units run the same FortiOS firmware build. If some cluster units are running different firmware builds, then unstable cluster operation may occur and the cluster units may not be able to synchronize correctly.

Re-installing the firmware build running on the primary unit forces the primary unit to upgrade all cluster units to the same firmware build.

---

## Console messages when configuration synchronization succeeds

When a cluster first forms, or when a new unit is added to a cluster as a subordinate unit, the following messages appear on the CLI console to indicate that the unit joined the cluster and had its configuring synchronized with the primary unit.

```
slave's configuration is not in sync with master's, sequence:0
slave's configuration is not in sync with master's, sequence:1
slave's configuration is not in sync with master's, sequence:2
slave's configuration is not in sync with master's, sequence:3
slave's configuration is not in sync with master's, sequence:4
slave starts to sync with master
logout all admin users
slave succeeded to sync with master
```

## Console messages when configuration synchronization fails

If you connect to the console of a subordinate unit that is out of synchronization with the primary unit, messages similar to the following are displayed.

```
slave is not in sync with master, sequence:0. (type 0x3)
slave is not in sync with master, sequence:1. (type 0x3)
slave is not in sync with master, sequence:2. (type 0x3)
slave is not in sync with master, sequence:3. (type 0x3)
slave is not in sync with master, sequence:4. (type 0x3)
global compared not matched
```

If synchronization problems occur the console message sequence may be repeated over and over again. The messages all include a type value (in the example `type 0x3`). The type value can help Fortinet Support diagnose the synchronization problem.

## Comparing checksums of cluster units

You can use the `diagnose sys ha showcsum` command to compare the configuration checksums of all cluster units. The output of this command shows checksums labelled `global` and `all` as well as checksums for each of the VDOMs including the `root` VDOM. The `get system ha-nonsync-csum` command can be used to display similar information; however, this command is intended to be used by FortiManager.

The primary unit and subordinate unit checksums should be the same. If they are not you can use the `execute ha synchronize` command to force a synchronization.

The following command output is for the primary unit of a cluster that does not have multiple VDOMs enabled:

```
diagnose sys ha showcsum
is_manage_master()=1, is_root_master()=1
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following command output is for a subordinate unit of the same cluster:

```
diagnose sys ha showcsum
is_manage_master()=0, is_root_master()=0
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following example shows using this command for the primary unit of a cluster with multiple VDOMs. Two VDOMs have been added named `test` and `Eng_vdm`.

From the primary unit:

```
config global
  sys ha showcsum
  is_manage_master()=1, is_root_master()=1
  debugzone
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe

## How to diagnose HA out of sync messages

This section describes how to use the commands `diagnose sys ha showcsum` and `diagnose debug` to diagnose the cause of HA out of sync messages.

If HA synchronization is not successful, use the following procedures on each cluster unit to find the cause.

### To determine why HA synchronization does not occur

1. Connect to each cluster unit CLI by connected to the console port.

2. Enter the following commands to enable debugging and display HA out of sync messages.

```
diagnose debug enable
diagnose debug console timestamp enable
diagnose debug application hataalk -1
diagnose debug application hasync -1
```

Collect the console output and compare the out of sync messages with the information in [Table 59 on page 1310](#).

3. Enter the following commands to turn off debugging.

```
diagnose debug disable
diagnose debug reset
```

### To determine what part of the configuration is causing the problem

If the previous procedure displays messages that include sync object 0x30 (for example, HA\_SYNC\_SETTING\_CONFIGURATION = 0x03) there is a synchronization problem with the configuration. Use the following steps to determine the part of the configuration that is causing the problem.

If your cluster consists of two cluster units, use this procedure to capture the configuration checksums for each unit. If your cluster consists of more than two cluster units, repeat this procedure for all cluster units that returned messages that include 0x30 sync object messages.

1. Connect to each cluster unit CLI by connected to the console port.
2. Enter the following command to turn on terminal capture  

```
diagnose debug enable
```
3. Enter the following command to stop HA synchronization.  

```
execute ha sync stop
```
4. Enter the following command to display configuration checksums.  

```
diagnose sys ha showcsum 1
```
5. Copy the output to a text file.
6. Repeat for all affected units.
7. Compare the text file from the primary unit with the text file from each cluster unit to find the checksums that do not match.

You can use a diff function to compare text files.

8. Repeat steps 4 to 7 for each checksum level:

```
diagnose sys ha showcsum 2
diagnose sys ha showcsum 3
diagnose sys ha showcsum 4
diagnose sys ha showcsum 5
diagnose sys ha showcsum 6
diagnose sys ha showcsum 7
diagnose sys ha showcsum 8
```

9. When the non-matching checksum is found, attempt to drill down further. This is possible for objects that have sub-components.

For example you can enter the following commands:

```
diagnose sys ha showcsum system.global
diagnose sys ha showcsum system.interface
```

Generally it is the first non-matching checksum in one of the levels that is the cause of the synchronization problem.

10. Attempt to can remove/change the part of the configuration that is causing the problem. You can do this by making configuration changes from the primary unit or subordinate unit CLI.

**11.** Enter the following commands to start HA configuration and stop debugging:

```
execute ha sync start
diagnose debug disable
diagnose debug reset
```

## Recalculating the checksums to resolve out of sync messages

Sometimes an error can occur when checksums are being calculated by the cluster. As a result of this calculation error the CLI console could display out of sync error messages even though the cluster is otherwise operating normally. You can also sometimes see checksum calculation errors in `diagnose sys ha showcsum` command output when the checksums listed in the `debugzone` output don't match the checksums in the `checksum` part of the output.

One solution to this problem could be to re-calculate the checksums. The re-calculated checksums should match and the out of sync error messages should stop appearing.

You can use the following command to re-calculate HA checksums:

```
diagnose sys ha csum-recalculate [<vdom-name> | global]
```

Just entering the command without options recalculates all checksums. You can specify a VDOM name to just recalculate the checksums for that VDOM. You can also enter `global` to recalculate the global checksum.

## Synchronizing kernel routing tables

In a functioning cluster, the primary unit keeps all subordinate unit kernel routing tables (also called the forwarding information base FIB) up to date and synchronized with the primary unit. After a failover, because of these routing table updates the new primary unit does not have to populate its kernel routing table before being able to route traffic. This gives the new primary unit time to rebuild its regular routing table after a failover.

Use the following command to view the regular routing table. This table contains all of the configured routes and routes acquired from dynamic routing protocols and so on. This routing table is not synchronized. On subordinate units this command will not produce the same output as on the primary unit.

```
get router info routing-table
```

Use the following command to view the kernel routing table (FIB). This is the list of resolved routes actually being used by the FortiOS kernel. The output of this command should be the same on the primary unit and the subordinate units.

```
get router info kernel
```

This section describes how clusters handle dynamic routing failover and also describes how to use CLI commands to control the timing of routing table updates of the subordinate unit routing tables from the primary unit.

## Configuring graceful restart for dynamic routing failover

When an HA failover occurs, neighbor routers will detect that the cluster has failed and remove it from the network until the routing topology stabilizes. During the time the routers may stop sending IP packets to the cluster and communications sessions that would normally be processed by the cluster may time out or be dropped. Also the new primary unit will not receive routing updates and so will not be able to build and maintain its routing database.

You can configure graceful restart (also called nonstop forwarding (NSF)) as described in [RFC3623](#) (Graceful OSPF Restart) to solve the problem of dynamic routing failover. If graceful

restart is enabled on neighbor routers, they will keep sending packets to the cluster following the HA failover instead of removing it from the network. The neighboring routers assume that the cluster is experiencing a graceful restart.

After the failover, the new primary unit can continue to process communication sessions using the synchronized routing data received from the failed primary unit before the failover. This gives the new primary unit time to update its routing table after the failover.

You can use the following commands to enable graceful restart or NSF on Cisco routers:

```
router ospf 1
  log-adjacency-changes
  nsf ietf helper strict-lsa-checking
```

If the cluster is running BGP, use the following command to enable graceful restart for BGP:

```
config router bgp
  set graceful-restart enable
end
```

You can also add BGP neighbors and configure the cluster unit to notify these neighbors that it supports graceful restart.

```
config router bgp
  config neighbor
    edit <neighbor_address_Ipv4>
      set capability-graceful-restart enable
    end
end
```

If the cluster is running OSPF, use the following command to enable graceful restart for OSFP:

```
config router ospf
  set restart-mode graceful-restart
end
```

To make sure the new primary unit keeps its synchronized routing data long enough to acquire new routing data, you should also increase the HA route time to live, route wait, and route hold values to 60 using the following CLI command:

```
config system ha
  set route-ttl 60
  set route-wait 60
  set route-hold 60
end
```

## Controlling how the FGCP synchronizes kernel routing table updates

You can use the following commands to control some of the timing settings that the FGCP uses when synchronizing kernel routing table updates from the primary unit to subordinate units and maintaining routes on the primary unit after a failover.

```
config system ha
  set route-hold <hold_integer>
  set route-ttl <ttl_integer>
  set route-wait <wait_integer>
end
```

## Change how long routes stay in a cluster unit routing table

Change the `route-ttl` time to control how long routes remain in a cluster unit routing table. The time to live range is 0 to 3600 seconds. The default time to live is 10 seconds.

The time to live controls how long routes remain active in a cluster unit routing table after the cluster unit becomes a primary unit. To maintain communication sessions after a cluster unit becomes a primary unit, routes remain active in the routing table for the route time to live while the new primary unit acquires new routes.

If `route-ttl` is set to 0 the primary unit must acquire all new routes before it can continue processing traffic. By default, `route-ttl` is set to 10 which may mean that only a few routes will remain in the routing table after a failover. Normally keeping `route-ttl` to 10 or reducing the value to 0 is acceptable because acquiring new routes usually occurs very quickly, especially if graceful restart is enabled, so only a minor delay is caused by acquiring new routes.

If the primary unit needs to acquire a very large number of routes, or if for other reasons, there is a delay in acquiring all routes, the primary unit may not be able to maintain all communication sessions.

You can increase the route time to live if you find that communication sessions are lost after a failover so that the primary unit can use synchronized routes that are already in the routing table, instead of waiting to acquire new routes.

## Change the time between routing updates

Change the `route-hold` time to change the time that the primary unit waits between sending routing table updates to subordinate units. The route hold range is 0 to 3600 seconds. The default route hold time is 10 seconds.

To avoid flooding routing table updates to subordinate units, set `route-hold` to a relatively long time to prevent subsequent updates from occurring too quickly. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Increasing the time between updates means that this data exchange will not have to happen so often.

The `route-hold` time should be coordinated with the `route-wait` time.

## Change the time the primary unit waits after receiving a routing update

Change the `route-wait` time to change how long the primary unit waits after receiving routing updates before sending the updates to the subordinate units. For quick routing table updates to occur, set `route-wait` to a relatively short time so that the primary unit does not hold routing table changes for too long before updating the subordinate units.

The `route-wait` range is 0 to 3600 seconds. The default `route-wait` is 0 seconds.

Normally, because the `route-wait` time is 0 seconds the primary unit sends routing table updates to the subordinate units every time its routing table changes.

Once a routing table update is sent, the primary unit waits the `route-hold` time before sending the next update.

Usually routing table updates are periodic and sporadic. Subordinate units should receive these changes as soon as possible so `route-wait` is set to 0 seconds. `route-hold` can be set to a relatively long time because normally the next route update would not occur for a while.

In some cases, routing table updates can occur in bursts. A large burst of routing table updates can occur if a router or a link on a network fails or changes. When a burst of routing table updates occurs, there is a potential that the primary unit could flood the subordinate units with routing table updates. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Setting `route-wait` to a

longer time reduces the frequency of additional updates and prevents flooding of routing table updates from occurring.

## Synchronizing IPsec VPN SAs

The FGCP synchronizes IPsec security associations (SAs) between cluster members so that if a failover occurs, the cluster can resume IPsec sessions without having to establish new SAs. The result is improved failover performance because IPsec sessions are not interrupted to establish new SAs. Also, establishing a large number of SAs can reduce cluster performance.

The FGCP implements slightly different synchronization mechanisms for IKEv1 and IKEv2.

### Synchronizing SAs for IKEv1

When an SA is synchronized to the subordinate units, the sequence number is set to the maximum sequence number. After a failover, all inbound traffic that connects with the new primary unit and uses the SA will be accepted without needing to re-key. However, first outbound packet to use the SA causes the sequence number to overflow and so causes the new primary unit to re-key the SA.

Please note the following:

- The cluster synchronizes all IPsec SAs.
- IPsec SAs are not synchronized until the IKE process has finished synchronizing the ISAKMP SAs. This is required in for dialup tunnels since it is the synchronizing of the ISAKMP SA that creates the dialup tunnel.
- A dialup interface is created as soon as the phase1 is complete. This ensures that the when HA synchronizes phase1 information the dialup name is included.
- If the IKE process re-starts for any reason it deletes any dialup tunnels that exist. This forces the peer to re-key them.
- IPsec SA deletion happens immediately. Routes associated with a dialup tunnel that is being deleted are cleaned up synchronously as part of the delete, rather than waiting for the SA hard-expiry.
- The FGCP does not sync the IPsec tunnel MTU from the primary unit to the subordinate units. This means that after HA failover if the first packet received by the FortiGate unit arrives after the HA route has been deleted and before the new route is added and the packet is larger than the default MTU of 1024 then the FortiGate unit sends back an ICMP fragmentation required. However, as soon as routing is re-established then the MTU will be corrected and traffic will flow.

### Synchronizing SAs for IKEv2

Due to the way the IKEv2 protocol is designed the FGCP cannot use exactly the same solution that is used for synchronizing IKEv1 SAs, though it is similar.

For IKEv2, like IKEv1, the FGCP synchronizes IKE and ISAKMP SAs from the primary unit to the subordinate units. However, for IKEv2 the FGCP cannot actually use this IKE SA to send/receive IKE traffic because IKEv2 includes a sequence number in every IKE message and thus it would require synchronizing every message to the subordinate units to keep the sequence numbers on the subordinate units up to date.

After a failover when the new primary unit accepts incoming IKEv2 sessions, as in IKEv1, the primary unit uses the synchronized SA to decrypt the traffic before passing it through to its destination. For outgoing sessions, because the synchronized SA has an old sequence number, the primary unit negotiates a new SA. This is different from IKEv1 where the existing SA is re-keyed.

Normally for IKEv2 the new primary unit could just negotiate a CHILD\_SA using the synchronized SA. However, because the sequence numbers are not up-to-date, as noted above, the synchronized SA cannot be used and the primary unit must instead negotiate a whole new SA.

## Link failover (port monitoring or interface monitoring)

Link failover means that if a monitored interface fails, the cluster reorganizes to reestablish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

You configure monitored interfaces (also called interface monitoring or port monitoring) by selecting the interfaces to monitor as part of the cluster HA configuration.

You can monitor up to 64 interfaces.

The interfaces that you can monitor appear on the port monitor list. You can monitor all FortiGate interfaces including redundant interfaces and 802.3ad aggregate interfaces.

You cannot monitor the following types of interfaces (you cannot select the interfaces on the port monitor list):

- FortiGate interfaces that contain an internal switch.
- VLAN subinterfaces.
- IPsec VPN interfaces.
- Individual physical interfaces that have been added to a redundant or 802.3ad aggregate interface.
- FortiGate-5000 series backplane interfaces that have not been configured as network interfaces.

If you are configuring a virtual cluster you can create a different port monitor configuration for each virtual cluster. Usually for each virtual cluster you would monitor the interfaces that have been added to the virtual domains in each virtual cluster.

Wait until after the cluster is up and running to enable interface monitoring. You do not need to configure interface monitoring to get a cluster up and running and interface monitoring will cause failovers if for some reason during initial setup a monitored interface has become disconnected. You can always enable interface monitoring once you have verified that the cluster is connected and operating properly.

You should only monitor interfaces that are connected to networks, because a failover may occur if you monitor an unconnected interface.

---

### To enable interface monitoring - web-based manager

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1. Connect to the cluster web-based manager.
2. Go to *System > Config > HA* and edit the primary unit (*Role* is *MASTER*).
3. Select the *Port Monitor* check boxes for the *port1* and *port2* interfaces and select *OK*.

The configuration change is synchronized to all cluster units.

## To enable interface monitoring - CLI

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1. Connect to the cluster CLI.
2. Enter the following command to enable interface monitoring for port1 and port2.

```
configure system ha
    set monitor port1 port2
end
```

The following example shows how to enable monitoring for the external, internal, and DMZ interfaces.

```
config system ha
    set monitor external internal dmz
end
```

With interface monitoring enabled, during cluster operation, the cluster monitors each cluster unit to determine if the monitored interfaces are operating and connected. Each cluster unit can detect a failure of its network interface hardware. Cluster units can also detect if its network interfaces are disconnected from the switch they should be connected to.

Cluster units cannot determine if the switch that its interfaces are connected to is still connected to the network. However, you can use remote IP monitoring to make sure that the cluster unit can connect to downstream network devices. See [“Remote link failover” on page 1325](#).

---

Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link between a network and the primary unit fails, to maintain communication with this network, the cluster must select a different primary unit; one that is still connected to the network. Unless another link failure has occurred, the new primary unit will have an active link to the network and will be able to maintain communication with it.

To support link failover, each cluster unit stores link state information for all monitored cluster units in a link state database. All cluster units keep this link state database up to date by sharing link state information with the other cluster units. If one of the monitored interfaces on one of the cluster units becomes disconnected or fails, this information is immediately shared with all cluster units.

## If a monitored interface on the primary unit fails

If a monitored interface on the primary unit fails, the cluster renegotiates to select a new primary unit using the process described in [“Primary unit selection” on page 1131](#). Because the cluster unit with the failed monitored interface has the lowest monitor priority, a different cluster unit becomes the primary unit. The new primary unit should have fewer link failures.

After the failover, the cluster resumes and maintains communication sessions in the same way as for a device failure. See [“Device failover” on page 1292](#).

## If a monitored interface on a subordinate unit fails

If a monitored interface on a subordinate unit fails, this information is shared with all cluster units. The cluster does not renegotiate. The subordinate unit with the failed monitored interface continues to function in the cluster.

In an active-passive cluster after a subordinate unit link failover, the subordinate unit continues to function normally as a subordinate unit in the cluster.

In an active-active cluster after a subordinate unit link failure:

- The subordinate unit with the failed monitored interface can continue processing connections between functioning interfaces. However, the primary unit stops sending sessions to a subordinate unit that use any failed monitored interfaces on the subordinate unit.
- If session pickup is enabled, all sessions being processed by the subordinate unit failed interface that can be are failed over to other cluster units. Sessions that cannot be failed over are lost and have to be restarted.
- If session pickup is not enabled all sessions being processed by the subordinate unit failed interface are lost.

## How link failover maintains traffic flow

Monitoring an interface means that the interface is connected to a high priority network. As a high priority network, the cluster should maintain traffic flow to and from the network, even if a link failure occurs. Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link that the primary unit has to a high priority network fails, to maintain traffic flow to and from this network, the cluster must select a different primary unit. This new primary unit should have an active link to the high priority network.

**Figure 210:**A link failure causes a cluster to select a new primary unit

If a monitored interface on the primary unit fails, the cluster renegotiates and selects the cluster unit with the highest monitor priority to become the new primary unit. The cluster unit with the highest monitor priority is the cluster unit with the most monitored interfaces connected to networks.

After a link failover, the primary unit processes all traffic and all subordinate units, even the cluster unit with the link failure, share session and link status. In addition all configuration changes, routes, and IPsec SAs are synchronized to the cluster unit with the link failure.

In an active-active cluster, the primary unit load balances traffic to all the units in the cluster. The cluster unit with the link failure can process connections between its functioning interfaces (for example if the cluster has connections to an internal, external, and DMZ network, the cluster unit with the link failure can still process connections between the external and DMZ networks).

If a monitored interface on a subordinate unit fails, the subordinate unit shares this information with all cluster units. The cluster does not renegotiate. The subordinate unit with the failed monitored interface continues to function in the cluster. In an active-active cluster, the subordinate unit can continue processing connections between functioning interfaces. The primary unit re-distributes traffic that was being processed by the failed interface of the subordinate unit to other cluster units. If session pickup is enabled, similar to a failover, some of these sessions continue while others must restart. See [“Session failover \(session pick-up\)” on page 1330](#).

## Recovery after a link failover and controlling primary unit selection (controlling falling back to the prior primary unit)

If you find and correct the problem that caused a link failure (for example, re-connect a disconnected network cable) the cluster updates its link state database and re-negotiates to select a primary unit.

What happens next depends on how the cluster configuration affects primary unit selection:

- The former primary unit will once again become the primary unit (falling back to becoming the primary unit)
- The primary unit will not change.

As described in [“Displaying cluster unit age differences” on page 1134](#), when the link is restored, if no options are configured to control primary unit selection and the cluster age difference is less than 300 seconds the former primary unit will once again become the primary unit. If the age differences are greater than 300 seconds then a new primary unit is not selected. Since you have no control on the age difference the outcome can be unpredictable. This is not a problem in cases where its not important which unit becomes the primary unit.

## Preventing a primary unit change after a failed link is restored

Some organizations will not want the cluster to change primary units when the link is restored. Instead they would rather wait to restore the primary unit during a maintenance window. This functionality is not directly supported, but you can experiment with changing some primary unit selection settings. For example, in most cases it should work to enable override on all cluster units and make sure their priorities are the same. This should mean that the primary unit should not change after a failed link is restored.

Then, when you want to restore the original primary unit during a maintenance window you can just set its Device Priority higher. After it becomes the primary unit you can reset all device priorities to the same value. Alternatively during a maintenance window you could reboot the current primary unit and any subordinate units except the one that you want to become the primary unit.

If the `override` CLI keyword is enabled on one or more cluster units and the device priority of a cluster unit is set higher than the others, when the link failure is repaired and the cluster unit with the highest device priority will always become the primary unit.

## Testing link failover

You can test link failure by disconnecting the network cable from a monitored interface of a cluster unit. If you disconnect a cable from a primary unit monitored interface the cluster should renegotiate and select one of the other cluster units as the primary unit. You can also verify that

traffic received by the disconnected interface continues to be processed by the cluster after the failover.

If you disconnect a cable from a subordinate unit interface the cluster will not renegotiate.

## Updating MAC forwarding tables when a link failover occurs

When a FortiGate HA cluster is operating and a monitored interface fails on the primary unit, the primary unit usually becomes a subordinate unit and another cluster unit becomes the primary unit. After a link failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables (also called arp tables) of the switches connected to the cluster. This is normal link failover operation (for more information, see [“Link failover \(port monitoring or interface monitoring\)” on page 1319](#)).

Even when gratuitous ARP packets are sent, some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur if the switch does not detect the failure and does not clear its MAC forwarding table.

You have another option available to make sure the switch detects the failover and clears its MAC forwarding tables. You can use the following command to cause a cluster unit with a monitored interface link failure to briefly shut down all of its interfaces (except the heartbeat interfaces) after the failover occurs:

```
config system ha
    set link-failed-signal enable
end
```

Usually this means each interface of the former primary unit is shut down for about a second. When this happens the switch should be able to detect this failure and clear its MAC forwarding tables of the MAC addresses of the former primary unit and pickup the MAC addresses of the new primary unit. Each interface will shut down for a second but the entire process usually takes a few seconds. The more interfaces the FortiGate unit has, the longer it will take.

Normally, the new primary unit also sends gratuitous ARP packets that also help the switch update its MAC forwarding tables to connect to the new primary unit. If `link-failed-signal` is enabled, sending gratuitous ARP packets is optional and can be disabled if you don't need it or if its causing problems. See [“Disabling gratuitous ARP packets after a failover” on page 1302](#).

## Multiple link failures

Every time a monitored interface fails, the cluster repeats the processes described above. If multiple monitored interfaces fail on more than one cluster unit, the cluster continues to negotiate to select a primary unit that can provide the most network connections.

## Example link failover scenarios

For the following examples, assume a cluster configuration consisting of two FortiGate units (FGT\_1 and FGT\_2) connected to three networks: internal using port2, external using port1, and DMZ using port3. In the HA configuration, the device priority of FGT\_1 is set higher than the unit priority of FGT\_2.

The cluster processes traffic flowing between the internal and external networks, between the internal and DMZ networks, and between the external and DMZ networks. If there are no link failures, FGT1 becomes the primary unit because it has the highest device priority.

The diagram illustrates a network setup for DMZ configuration on a MikroTik router. The router has two main ports: Port1 (WAN) and Port2 (LAN). Port1 is connected to the Internet via a Router. Port2 is connected to a Switch, which is connected to an Internal Network. A DMZ Network is also connected to the router. The diagram shows the configuration of Port2 Interface Monitoring and Port1 Interface Monitoring.

If the port1 link on FGT\_1 fails, FGT\_2 becomes primary unit because it has fewer interfaces with a link failure. If the cluster is operating in active-active mode, the cluster load balances traffic between the internal network (port2) and the DMZ network (port3). Traffic between the Internet (port1) and the internal network (port2) and between the Internet (port1) and the DMZ network (port3) is processed by the primary unit only.

If port2 on FGT\_1 and port1 on FGT\_2 fail, then FGT\_1 becomes the primary unit. After both of these link failures, both cluster units have the same monitor priority. So the cluster unit with the highest device priority (FGT\_1) becomes the primary unit.

## Subsecond failover

For interfaces that do not support subsecond failover, port monitoring regularly polls the connection status of monitored interfaces. When a check finds that an interface has gone down, port monitoring causes a link failover. Subsecond failover results in a link failure being detected sooner because the system doesn't have to wait for the next poll to find out about the failure.

Subsecond failover requires interfaces that support sending the link failure system call. This functionality is available for:

- Interfaces with network processors (NPx)
- Interfaces with content processors (CP4, CP5, CP6, etc.)
- Interfaces in Fortinet Mezzanine Cards that include network and content processors (FMC-XD2, FMC-XG2, etc.)
- Accelerated interface modules (FortiGate-ASM-FB4, ADM-FB8, ADM-XB2, ADM-XD4, RTM-XD2 etc).
- Interfaces in security processor modules (FortiGate-ASM-CE4, ASM-XE2, etc)

Subsecond failover can accelerate HA failover to reduce the link failover time to less than one second under ideal conditions. Actual failover performance may vary depending on traffic patterns and network configuration. For example, some network devices may respond slowly to an HA failover.

No configuration changes are required to support subsecond failover. However, for best subsecond failover results, the recommended heartbeat interval is 100ms and the recommended lost heartbeat threshold is 5. (See [“Changing the heartbeat interval” on page 1298](#))

```
config system ha
    set hb-lost-threshold 5
    set hb-interval 1
end
```

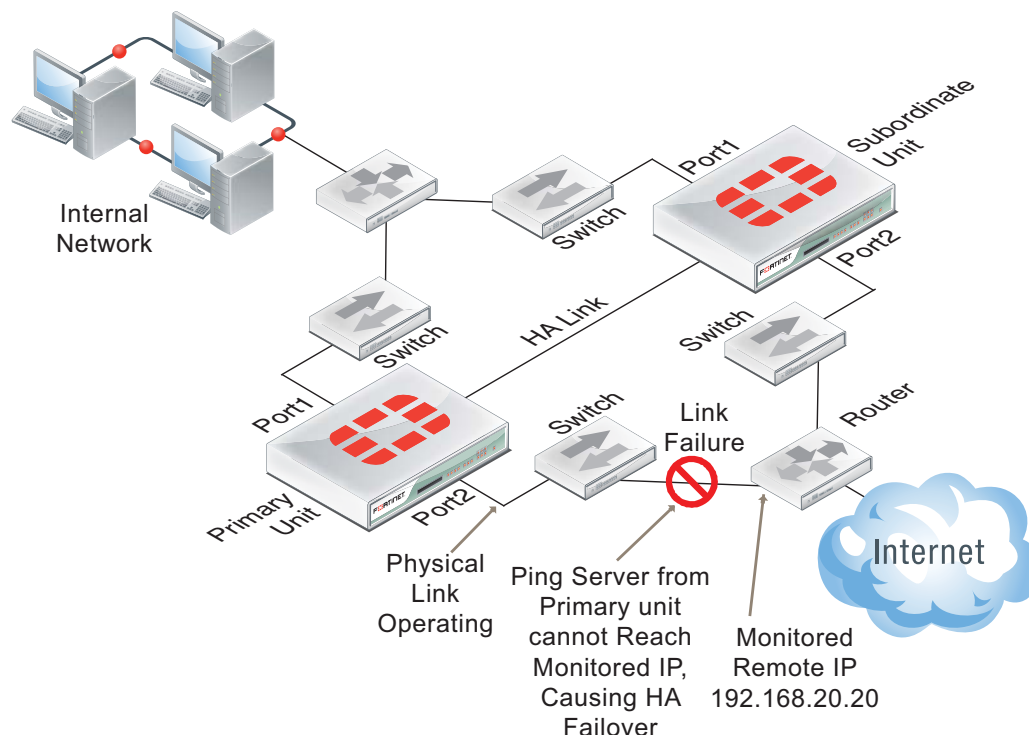

For information about how to reduce failover times, see [“Failover performance” on page 1340](#).

## Remote link failover

Remote link failover (also called remote IP monitoring) is similar to HA port monitoring and interface dead gateway detection. Port monitoring causes a cluster to failover if a monitored primary unit interface fails or is disconnected. Remote IP monitoring uses ping servers configured for FortiGate interfaces on the primary unit to test connectivity with IP addresses of network devices. Usually these would be IP addresses of network devices not directly connected to the cluster. For example, a downstream router. Remote IP monitoring causes a failover if one or more of these remote IP addresses does not respond to a ping server.

By being able to detect failures in network equipment not directly connected to the cluster, remote IP monitoring can be useful in a number of ways depending on your network configuration. For example, in a full mesh HA configuration, with remote IP monitoring, the cluster can detect failures in network equipment that is not directly connected to the cluster but that would interrupt traffic processed by the cluster if the equipment failed.

**Figure 212:**Example HA remote IP monitoring topology

In the simplified example topology shown in [Figure 212](#), the switch connected directly to the primary unit is operating normally but the link on the other side of the switches fails. As a result traffic can no longer flow between the primary unit and the Internet.

To detect this failure you can create a remote IP monitoring configuration consisting of a ping server dead gateway detection configuration for port2 of the cluster. The primary unit tests connectivity to 192.168.20.20. If the ping server cannot connect to 192.268.20.20 the cluster to fails over and the subordinate unit becomes the new primary unit. The remote HA monitoring ping server on the new primary unit can connect to 192.168.20.20 so the failover maintains connectivity between the internal network and the Internet through the cluster.

### To configure remote IP monitoring

1. Enter the following commands to configure HA remote monitoring for the example topology.

- Enter the `pingserver-monitor-interface` keyword to enable HA remote IP monitoring on port2.
- Leave the `pingserver-failover-threshold` set to the default value of 0. You can change this value if you do not want a failover to occur if only one ping server fails.
- Enter the `pingserver-flip-timeout` keyword to set the flip timeout to 120 minutes. After a failover, if HA remote IP monitoring on the new primary unit also causes a failover, the flip timeout prevents the failover from occurring until the timer runs out. Setting the `pingserver-flip-timeout` to 120 means that remote IP monitoring can only cause a failover every 120 minutes. This flip timeout is required to prevent repeating failovers if remote IP monitoring causes a failover from all cluster units because none of the cluster units can connect to the monitored IP addresses.

```
config system ha
    set pingserver-monitor-interface port2
    set pingserver-failover-threshold 0
    set pingserver-flip-timeout 120
end
```

2. Enter the following commands to add the ping server for the port2 interface and to set the HA remote IP monitoring priority for this ping server.
  - Enter the `detectserver` keyword to add the ping server and set the ping server IP address to 192.168.20.20.
  - Leave the `ha-priority` keyword set to the default value of 1. You only need to change this priority if you change the HA ping server failover threshold.

The `ha-priority` setting is not synchronized among cluster units. So if you want to change the `ha-priority` setting you must change it separately on each cluster unit. Otherwise it will remain set to the default value of 1.

- Use the `interval` keyword to set the time between ping server pings and use the `failtime` keyword to set the number of times that the ping can fail before a failure is detected (the failover threshold). The following example reduces the failover threshold to 2 but keeps the ping interval at the default value of 5.

```
config router gwdetect
  edit port2
    set server 192.168.20.20
    set ha-priority 1
    set interval 5
    set failtime 2
  end
```

You can also do this from the web-based manager by going to *Router > Static > Settings*, selecting *Create New* to add a new dead gateway detection configuration, setting *Ping Server* to 192.168.20.20, *HA Priority* to 1, *Ping Interval* to 5, and *Failover Threshold* to 2.

## Adding HA remote IP monitoring to multiple interfaces

You can enable HA remote IP monitoring on multiple interfaces by adding more interface names to the `pingserver-monitor-interface` keyword. If your FortiGate configuration includes VLAN interfaces, aggregate interfaces and other interface types, you can add the names of these interfaces to the `pingserver-monitor-interface` keyword to configure HA remote IP monitoring for these interfaces.

For example, enable remote IP monitoring for interfaces named port2, port20, and vlan\_234:

```
config system ha
  set pingserver-monitor-interface port2 port20 vlan_234
  set pingserver-failover-threshold 10
  set pingserver-flip-timeout 120
end
```

Then configure ping servers for each of these interfaces. In the following example, default values are accepted for all settings other than the server IP address.

```
config router gwdetect
  edit port2
    set server 192.168.20.20
  next
  edit port20
    set server 192.168.20.30
  next
  edit vlan_234
    set server 172.20.12.10
  end
```

## Changing the ping server failover threshold

By default the ping server failover threshold is 0 and the HA priority is 1 so any HA remote IP monitoring ping server failure causes a failover. If you have multiple ping servers you may want a failover to occur only if more than one of them has failed.

For example, you may have 3 ping servers configured on three interfaces but only want a failover to occur if two of the ping servers fail. To do this you must set the HA priorities of the ping servers and the HA ping server failover threshold so that the priority of one ping server is less than the failover threshold but the added priorities of two ping servers is equal to or greater than the failover threshold. Failover occurs when the HA priority of all failed ping servers reaches or exceeds the threshold.

For example, set the failover threshold to 10 and monitor three interfaces:

```
config system ha
  set pingserver-monitor-interface port2 port20 vlan_234
  set pingserver-failover-threshold 10
  set pingserver-flip-timeout 120
end
```

Then set the HA priority of each ping server to 5.

The HA Priority (`ha-priority`) setting is not synchronized among cluster units. In the following example, you must set the HA priority to 5 by logging into each cluster unit.

---

```

config router gwdetect
  edit port2
    set server 192.168.20.20
    set ha-priority 5
  next
  edit port20
    set server 192.168.20.30
    set ha-priority 5
  next
  edit vlan_234
    set server 172.20.12.10
    set ha-priority 5
  end

```

If only one of the ping servers fails, the total ping server HA priority will be 5, which is lower than the failover threshold so a failover will not occur. If a second ping server fails, the total ping server HA priority of 10 will equal the failover threshold, causing a failover.

By adding multiple ping servers to the remote HA monitoring configuration and setting the HA priorities for each, you can fine tune remote IP monitoring. For example, if it is more important to maintain connections to some networks you can set the HA priorities higher for these ping servers. And if it is less important to maintain connections to other networks you can set the HA priorities lower for these ping servers. You can also adjust the failover threshold so that if the cluster cannot connect to one or two high priority IP addresses a failover occurs. But a failover will not occur if the cluster cannot connect to one or two low priority IP addresses.

## Monitoring multiple IP addresses from one interface

You can add multiple IP addresses to a single ping server to use HA remote IP monitoring to monitor more than one IP address from a single interface. If you add multiple IP addresses, the ping will be sent to all of the addresses at the same time. The ping server only fails when no responses are received from any of the addresses.

```

config router gwdetect
  edit port2
    set server 192.168.20.20 192.168.20.30 172.20.12.10
  end

```

## Flip timeout

The HA remote IP monitoring configuration also involves setting a flip timeout. The flip timeout is required to reduce the frequency of failovers if, after a failover, HA remote IP monitoring on the new primary unit also causes a failover. This can happen if the new primary unit cannot connect to one or more of the monitored remote IP addresses. The result could be that until you fix the network problem that blocks connections to the remote IP addresses, the cluster will experience repeated failovers. You can control how often the failovers occur by setting the flip timeout. The flip timeout stops HA remote IP monitoring from causing a failover until the primary unit has been operating for the duration of the flip timeout.

If you set the flip timeout to a relatively high number of minutes you can find and repair the network problem that prevented the cluster from connecting to the remote IP address without the cluster experiencing very many failovers. Even if it takes a while to detect the problem, repeated failovers at relatively long time intervals do not usually disrupt network traffic.

## Detecting HA remote IP monitoring failovers

Just as with any HA failover, you can detect HA remote IP monitoring failovers by using SNMP to monitor for HA traps. You can also use alert email to receive notifications of HA status changes and monitor log messages for HA failover log messages. In addition, FortiGate units send the critical log message `Ping Server is down` when a ping server fails. The log message includes the name of the interface that the ping server has been added to.

## Session failover (session pick-up)

Session failover means that a cluster maintains active network TCP and IPsec VPN sessions (including NAT sessions) after a device or link failover. You can also configure session failover to maintain UDP and ICMP sessions. Session failover does not failover multicast, or SSL VPN sessions.

FortiGate HA does not support session failover by default. To enable session failover go to *System > Config > HA* and select *Enable Session Pick-up*.

From the CLI enter:

```
config system ha
    set session-pickup enable
end
```

To support session failover, when *Enable Session Pick-up* is selected, the FGCP maintains an HA session table for most TCP communication sessions being processed by the cluster and synchronizes this session table with all cluster units. If a cluster unit fails, the HA session table information is available to the remaining cluster units and these cluster units use this session table to resume most of the TCP sessions that were being processed by the failed cluster unit without interruption.

If session pickup is enabled, you can use the following command to also enable UDP and ICMP session failover:

```
config system ha
    set session-pickup-connectionless enable
end
```

You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce CPU usage and reduce HA heartbeat network bandwidth usage.

## If session pickup is not selected

If *Enable Session Pick-up* is not selected, the FGCP does not maintain an HA session table and most TCP sessions do not resume after a failover. After a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates.

Many protocols can successfully restart sessions with little, if any, loss of data. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Since most HTTP sessions are very short, in most cases they will not even notice an interruption unless they are downloading large files. Users downloading a large file may have to restart their download after a failover.

Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.

Some sessions may resume after a failover whether or not enable session pick-up is selected:

- “UDP, ICMP, multicast and broadcast packet session failover” on page 1334
- “FortiOS Carrier GTP session failover” on page 1334
- “Active-active HA subordinate units sessions can resume after a failover” on page 1335.

## Improving session synchronization performance

Two HA configuration options are available to reduce the performance impact of enabling session pickup. They include reducing the number of sessions that are synchronized by adding a session pickup delay and using more FortiGate interfaces for session synchronization.

### Reducing the number of sessions that are synchronized

Enable the `session-pickup-delay` CLI option to reduce the number of sessions that are synchronized by synchronizing sessions only if they remain active for more than 30 seconds. Enabling this option could greatly reduce the number of sessions that are synchronized if a cluster typically processes very many short duration sessions, which is typical of most HTTP traffic for example.

Use the following command to enable a 30 second session pickup delay:

```
config system ha
    set session-pickup-delay enable
end
```

Enabling session pickup delay means that if a failover occurs more sessions may not be resumed after a failover. In most cases short duration sessions can be restarted with only a minor traffic interruption. However, if you notice too many sessions not resuming after a failover you might want to disable this setting.

### Using multiple FortiGate interfaces for session synchronization

Using the `session-sync-dev` option you can select one or more FortiGate interfaces to use for synchronizing sessions as required for session pickup. Normally session synchronization occurs over the HA heartbeat link. Using this HA option means only the selected interfaces are used for session synchronization and not the HA heartbeat link. If you select more than one interface, session synchronization traffic is load balanced among the selected interfaces.

Moving sessions synchronization from the HA heartbeat interface reduces the bandwidth requirements of the HA heartbeat interface and may improve the efficiency and performance of the cluster, especially if the cluster is synchronizing a large number of sessions. Load balancing session synchronization among multiple interfaces can further improve performance and efficiency if the cluster is synchronizing a large number of sessions.

Use the following command to perform cluster session synchronization using the port10 and port12 interfaces.

```
config system ha
    set session-sync-dev port10 port12
end
```

Session synchronization packets use Ethertype 0x8892. The interfaces to use for session synchronization must be connected together either directly using the appropriate cable (possible if there are only two units in the cluster) or using switches. If one of the interfaces becomes disconnected the cluster uses the remaining interfaces for session synchronization. If all of the session synchronization interfaces become disconnected, session synchronization reverts back to using the HA heartbeat link. All session synchronization traffic is between the primary unit and each subordinate unit.

Since large amounts of session synchronization traffic can increase network congestion, it is recommended that you keep this traffic off of your network by using dedicated connections for it.

## Session failover not supported for all sessions

Most of the features applied to sessions by FortiGate UTM functionality require the FortiGate unit to maintain very large amounts of internal state information for each session. The FGCP does not synchronize internal state information for the following UTM features, so the following types of sessions will not resume after a failover:

- Virus scanning of HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, CIFS, and NNTP sessions,
- Web filtering and FortiGuard Web Filtering of HTTP and HTTPS sessions,
- Spam filtering of IMAP, IMAPS, POP3, POP3S, SMTP, and SMTPS sessions,
- DLP scanning of IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, SIP, SIMPLE, and SCCP sessions,
- DLP archiving of HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, SMTP, SMTPS, IM, NNTP, AIM, ICQ, MSN, Yahoo! IM, SIP, SIMPLE, and SCCP signal control sessions,

Active-active clusters can resume some of these sessions after a failover. See [“Active-active HA subordinate units sessions can resume after a failover” on page 1335](#) for details.

If you use these features to protect most of the sessions that your cluster processes, enabling session failover may not actually provide significant session failover protection.

TCP sessions that are not being processed by these UTM features resume after a failover even if these sessions are accepted by security policies with UTM options configured. Only TCP sessions that are actually being processed by these UTM features do not resume after a failover. For example:

- TCP sessions that are not virus scanned, web filtered, spam filtered, content archived, or are not SIP, SIMPLE, or SCCP signal traffic resume after a failover, even if they are accepted by a security policy with UTM options enabled. For example, SNMP TCP sessions resume after a failover because FortiOS does not apply any UTM options to SNMP sessions.
- TCP sessions for a protocol for which UTM features have not been enabled resume after a failover even if they are accepted by a security policy with UTM features enabled. For example, if you have not enabled any antivirus or content archiving settings for FTP, FTP sessions resume after a failover.

The following UTM features do not affect TCP session failover:

- IPS does not affect session failover. Sessions being scanned by IPS resume after a failover. After a failover; however, IPS can only perform packet-based inspection of resumed sessions; reducing the number of vulnerabilities that IPS can detect. This limitation only applies to in-progress resumed sessions.
- Application control does not affect session failover. Sessions that are being monitored by application control resume after a failover.
- Logging enabled from UTM features does not affect session failover. UTM logging writes event log messages for UTM events; such as when a virus is found by antivirus scanning, when Web Filtering blocks a URL, and so on. Logging does not enable features that would prevent sessions from being failed over, logging just reports on the activities of enabled features.

If more than one UTM feature is applied to a TCP session, that session will not resume after a failover as long as one of the UTM features prevents session failover. For example:

- Sessions being scanned by IPS and also being virus scanned do not resume after a failover.
- Sessions that are being monitored by application control and that are being DLP archived or virus scanned will not resume after a failover.

## IPv6, NAT64, and NAT66 session failover

The FGCP supports IPv6, NAT64, and NAT66 session failover, if session pickup is enabled, these sessions are synchronized between cluster members and after an HA failover the sessions will resume with only minimal interruption.

## SIP session failover

The FGCP supports SIP session failover (also called stateful failover) for active-passive HA. To support SIP session failover, create a standard HA configuration and select *Enable Session Pick-up* option.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in-progress SIP calls (setup complete) and their RTP flows are maintained and the calls will continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA failover occurs. But in most cases the call setup should be able to continue after the failover.

## Explicit web proxy, WCCP, and WAN optimization session failover

Similar to UTM sessions, the explicit web proxy, WCCP and WAN optimization features all require the FortiGate unit to maintain very large amounts of internal state information for each session. This information is not maintained and these sessions do not resume after a failover.

## SSL offloading and HTTP multiplexing session failover

SSL offloading and HTTP multiplexing are both enabled from firewall virtual IPs and firewall load balancing. Similar to the features applied by UTM, SSL offloading and HTTP multiplexing requires the FortiGate unit to maintain very large amounts of internal state information for each session. Sessions accepted by security policies containing virtual IPs or virtual servers with SSL offloading or HTTP multiplexing enabled do not resume after a failover.

## IPsec VPN session failover

Session failover is supported for all IPsec VPN tunnels. To support IPsec VPN tunnel failover, when an IPsec VPN tunnel starts, the FGCP distributes the SA and related IPsec VPN tunnel data to all cluster units.

## SSL VPN session failover and SSL VPN authentication failover

Session failover is not supported for SSL VPN tunnels. However, authentication failover is supported for the communication between the SSL VPN client and the FortiGate unit. This means that after a failover, SSL VPN clients can re-establish the SSL VPN session between the SSL VPN client and the FortiGate unit without having to authenticate again.

However, all sessions inside the SSL VPN tunnel that were running before the failover are stopped and have to be restarted. For example, file transfers that were in progress would have to be restarted. As well, any communication sessions with resources behind the FortiGate unit that are started by an SSL VPN session have to be restarted.

To support SSL VPN cookie failover, when an SSL VPN session starts, the FGCP distributes the cookie created to identify the SSL VPN session to all cluster units.

## PPTP and L2TP VPN sessions

PPTP and L2TP VPNs are supported in HA mode. For a cluster you can configure PPTP and L2TP settings and you can also add security policies to allow PPTP and L2TP pass through. However, the FGCP does not provide session failover for PPTP or L2TP. After a failover, all active PPTP and L2TP sessions are lost and must be restarted.

## UDP, ICMP, multicast and broadcast packet session failover

By default, even with session pickup enabled, the FGCP does not maintain a session table for UDP, ICMP, multicast, or broadcast packets. So the cluster does not specifically support failover of these packets.

Some UDP traffic can continue to flow through the cluster after a failover. This can happen if, after the failover, a UDP packet that is part of an already established communication stream matches a security policy. Then a new session will be created and traffic will flow. So after a short interruption, UDP sessions can appear to have failed over. However, this may not be reliable for the following reasons:

- UDP packets in the direction of the security policy must be received before reply packets can be accepted. For example, if a port1 -> port2 policy accepts UDP packets, UDP packets received at port2 destined for the network connected to port1 will not be accepted until the policy accepts UDP packets at port1 that are destined for the network connected to port2. So, if a user connects from an internal network to the Internet and starts receiving UDP packets from the Internet (for example streaming media), after a failover the user will not receive any more UDP packets until the user re-connects to the Internet site.
- UDP sessions accepted by NAT policies will not resume after a failover because NAT will usually give the new session a different source port. So only traffic for UDP protocols that can handle the source port changing during a session will continue to flow.

You can however, enable session pickup for UDP and ICMP packets by enabling session pickup for TCP sessions and then enabling session pickup for connectionless sessions:

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

This configuration causes the cluster units to synchronize UDP and ICMP session tables and if a failover occurs UDP and ICMP sessions are maintained.

## FortiOS Carrier GTP session failover

FortiOS Carrier HA supports GTP session failover. The primary unit synchronizes the GTP tunnel state to all cluster units after the GTP tunnel setup is completed. After the tunnel setup is completed, GTP sessions use UDP and HA does not synchronize UDP sessions to all cluster units. However, similar to other UDP sessions, after a failover, since the new primary unit will have the GTP tunnel state information, GTP UDP sessions using the same tunnel can continue to flow with some limitations.

The limitation on packets continuing to flow is that there has to be a security policy to accept the packets. For example, if the FortiOS Carrier unit has an internal to external security policy, GTP UDP sessions using an established tunnel that are received by the internal interface are accepted by the security policy and can continue to flow. However, GTP UDP packets for an established tunnel that are received at the external interface cannot flow until packets from the same tunnel are received at the internal interface.

If you have bi-directional policies that accept GTP UDP sessions then traffic in either direction that uses an established tunnel can continue to flow after a failover without interruption.

## Active-active HA subordinate units sessions can resume after a failover

In an active-active cluster, subordinate units process sessions. After a failover, all cluster units that are still operating may be able to continue processing the sessions that they were processing before the failover. These sessions are maintained because after the failover the new primary unit uses the HA session table to continue to send session packets to the cluster units that were processing the sessions before the failover. Cluster units maintain their own information about the sessions that they are processing and this information is not affected by the failover. In this way, the cluster units that are still operating can continue processing their own sessions without loss of data.

The cluster keeps processing as many sessions as it can. But some sessions can be lost. Depending on what caused the failover, sessions can be lost in the following ways:

- A cluster unit fails (the primary unit or a subordinate unit). All sessions that were being processed by that cluster unit are lost.
- A link failure occurs. All sessions that were being processed through the network interface that failed are lost.

This mechanism for continuing sessions is not the same as session failover because:

- Only the sessions that can be are maintained.
- The sessions are maintained on the same cluster units and not re-distributed.
- Sessions that cannot be maintained are lost.

## WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended HA configuration for WAN optimization is active-passive mode. Also, when the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions. HA also does not support WAN optimization session failover.

In a cluster, the primary unit only stores web cache and byte cache databases. These databases are not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its web and byte caches. As well, the new primary unit cannot connect to a SAS partition that the failed primary unit used.

Rebuilding the byte caches can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate units that it is participating with in WAN optimization tunnels.

## Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time experienced by your network users may depend on how quickly the switches

connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

## Monitoring cluster units for failover

You can use logging and SNMP to monitor cluster units for failover. Both the primary and subordinate units can be configured to write log messages and send SNMP traps if a failover occurs. You can also log into the cluster web-based manager and CLI to determine if a failover has occurred. See [“Monitoring cluster units for failover” on page 1277](#).

## NAT/Route mode active-passive cluster packet flow

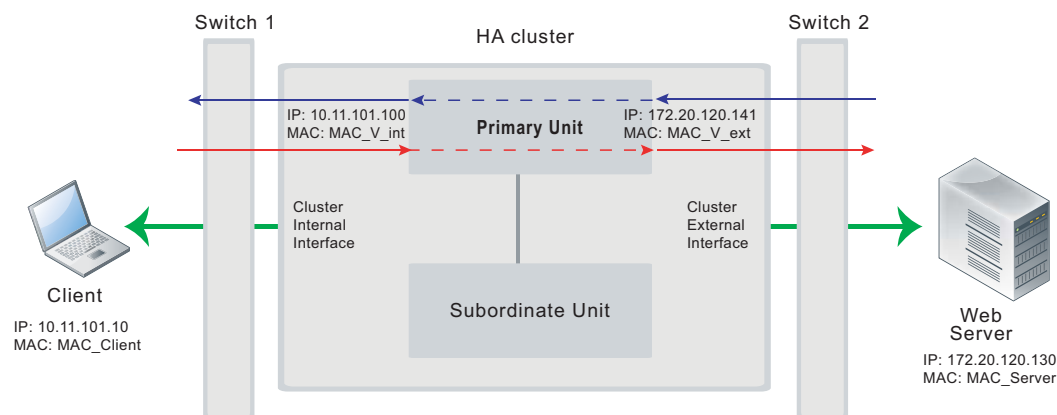

This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in NAT/Route mode. In the example, the NAT/Route mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the Internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In an active-passive cluster operating in NAT/Route mode, four MAC addresses are involved in communication between the client and the web server when the primary unit processes the connection:

- Internal virtual MAC address (MAC\_V\_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC\_V\_ext) assigned to the primary unit external interface,
- Client MAC address (MAC\_Client),
- Server MAC address (MAC\_Server),

In NAT/Route mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC\_V\_int) and the server only know the cluster external virtual MAC address (MAC\_V\_ext). Cluster virtual MAC addresses are described in [“Cluster virtual MAC addresses” on page 1300](#).

**Figure 213:**NAT/Route mode active-passive packet flow

### Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC\_V\_int) which corresponds to its IP address of 10.11.101.100.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
<b>Source</b>	10.11.101.10	MAC_Client
<b>Destination</b>	172.20.120.130	MAC_V_int

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the web server.

	IP address	MAC address
<b>Source</b>	172.20.120.141	MAC_V_ext
<b>Destination</b>	172.20.120.130	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

### Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC\_V\_ext) which corresponds its IP address of 172.20.120.141.

4. The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5. The primary unit processes the packet.
6. The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_V_int
Destination	10.11.101.10	MAC_Client

7. The primary unit continues to process packets in this way unless a failover occurs.

## When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails the subordinate unit becomes the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.  
The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.
3. The new primary unit sends gratuitous ARP packets from the internal interface to the 10.11.101.0 network to associate its internal IP address with the internal virtual MAC address.
4. The new primary unit sends gratuitous ARP packets to the 172.20.120.0 to associate its external IP address with the external virtual MAC address.
5. Traffic sent to the cluster is now received and processed by the new primary unit.  
If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

## Transparent mode active-passive cluster packet flow

This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in Transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the Transparent mode cluster.

In an active-passive cluster operating in Transparent mode, two MAC addresses are involved in the communication between a client and a server when the primary unit processes a connection:

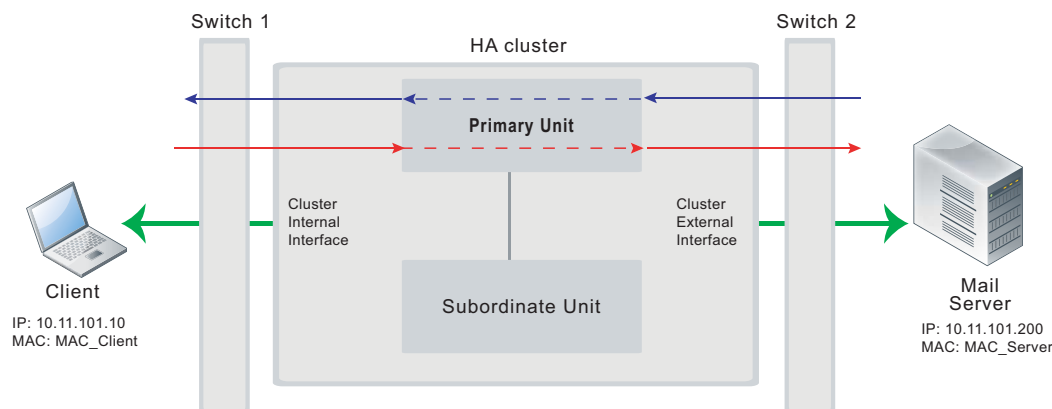

- Client MAC address (MAC\_Client)
- Server MAC address (MAC\_Server)

The HA virtual MAC addresses are not directly involved in communication between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and processed by the cluster.

The cluster's presence on the network is transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the HA virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the HA virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

**Figure 214:**Transparent mode active-passive packet flow

### Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 110.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC\_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
<b>Source</b>	10.11.101.10	MAC_Client
<b>Destination</b>	10.11.101.200	MAC_Server

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
<b>Source</b>	10.11.101.10	MAC_Client
<b>Destination</b>	10.11.101.200	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

### Packet flow from mail server to client

1. To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
2. The primary unit forwards the ARP request to the client computer.

3. The client computer responds with its MAC address (MAC\_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.
4. The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
<b>Source</b>	10.11.101.200	MAC_Server
<b>Destination</b>	10.11.101.10	MAC_Client

5. The primary unit processes the packet.
6. The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
<b>Source</b>	10.11.101.200	MAC_Server
<b>Destination</b>	10.11.101.10	MAC_Client

7. The primary unit continues to process packets in this way unless a failover occurs.

## When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails, the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.
3. The new primary unit sends gratuitous ARP packets to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.
4. The new primary unit sends gratuitous ARP packets to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.
5. Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

## Failover performance

This section describes the designed device and link failover times for a FortiGate cluster and also shows results of a failover performance test.

### Device failover performance

By design FGCP device failover time is 2 seconds for a two-member cluster with ideal network and traffic conditions. If subsecond failover is enabled the failover time can drop below 1 second.

All cluster units regularly receive HA heartbeat packets from all other cluster units over the HA heartbeat link. If any cluster unit does not receive a heartbeat packet from any other cluster unit for 2 seconds, the cluster unit that has not sent heartbeat packets is considered to have failed.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions. Typically if subsecond failover is not enabled you can expect a failover time of 9 to 15 seconds depending on the cluster and network configuration. The failover time can also be increased by more complex configurations and or configurations with network equipment that is slow to respond.

You can change the `hb-lost-threshold` to increase or decrease the device failover time. See [“Modifying heartbeat timing” on page 1298](#) for information about using `hb-lost-threshold`, and other heartbeat timing settings.

## Link failover performance

Link failover time is controlled by how long it takes for a cluster to synchronize the cluster link database. When a link failure occurs, the cluster unit that experienced the link failure uses HA heartbeat packets to broadcast the updated link database to all cluster units. When all cluster units have received the updated database the failover is complete.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions.

## Reducing failover times

You can do the following to help reduce failover times:

- Keep the network configuration as simple as possible with as few as possible network connections to the cluster.
- If possible operate the cluster in Transparent mode.
- Use high-performance switches to that the switches failover to interfaces connected to the new primary unit as quickly as possible.
- Use accelerated FortiGate interfaces. In some cases accelerated interfaces will reduce failover times.
- Make sure the FortiGate unit sends multiple gratuitous arp packets after a failover. In some cases, sending more gratuitous arp packets will cause connected network equipment to recognize the failover sooner. To send 10 gratuitous arp packets:

```
config system ha
    set arps 10
end
```

- Reduce the time between gratuitous arp packets. This may also caused connected network equipment to recognize the failover sooner. To send 50 gratuitous arp packets with 1 second between each packet:

```
config system ha
    set arp 50
    set arps-interval 1
end
```

- Reduce the number of lost heartbeat packets and reduce the heartbeat interval timers to be able to more quickly detect a device failure. To set the lost heartbeat threshold to 3 packets and the heartbeat interval to 100 milliseconds:

```
config system ha
    set hb-interval 3
    set hb-lost-threshold 1
end
```

- Reduce the hello state hold down time to reduce the amount of the time the cluster waits before transitioning from the hello to the work state. To set the hello state hold down time to 5 seconds:

```
config system ha
    set helo-holddown 5
end
```

- Enable sending a link failed signal after a link failover to make sure that attached network equipment responds a quickly as possible to a link failure. To enable the link failed signal:

```
config system ha
    set link-failed-signal enable
end
```

# HA and load balancing

FGCP active-active load balancing distributes network traffic among all of the units in a cluster. Load balancing can improve cluster performance because the processing load is shared among multiple cluster units.

This chapter describes how active-active load balancing works and provides detailed NAT/Route and Transparent mode packet flow descriptions.

This chapter contains the following sections:

- [Load balancing overview](#)
- [Configuring load balancing settings](#)
- [NAT/Route mode active-active cluster packet flow](#)
- [Transparent mode active-active cluster packet flow](#)

## Load balancing overview

In active-active HA, the FGCP uses a technique similar to unicast load balancing in which the primary unit is associated with the cluster HA virtual MAC addresses and cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster.

An active-active HA cluster consists of a primary unit that processes communication sessions and one or more subordinate units that also process communication sessions. The primary unit receives all sessions and load balances sessions for security policies with UTM enabled to all cluster units. Communication between the cluster units uses the actual cluster unit MAC addresses.

Processing UTM sessions can be CPU and memory-intensive, load balancing UTM traffic may result in an active-active cluster having higher throughput than an active-passive cluster or a standalone FortiGate unit because resource-intensive UTM processing is distributed among all cluster units.

You can also enable the `load-balance-all` CLI keyword to have the primary unit load balance all TCP sessions. Load balancing TCP sessions is less likely to improve throughput because of extra overhead required for load balancing. So `load-balance-all` is disabled by default.

You can also enable the `load-balance-udp` CLI keyword to have the primary unit load balance all UDP sessions. Load balancing UDP sessions will also increase overhead so it is disabled by default.

During active-active HA load balancing operation, when the primary unit receives the first packet of a UTM session (or a TCP session if `load-balance-all` is enabled or a UDP session if `load-balance-udp` is enabled) the primary unit uses the configured load balancing schedule to determine the cluster unit that will process the session. The primary unit stores the load balancing information for each active load balanced session in the cluster load balancing session table. Using the information in this table, the primary unit can then forward all of the remaining packets in each session to the appropriate cluster unit. The load balancing session table is synchronized among all cluster units.

ICMP, multicast, and broadcast sessions are never load balanced and are always processed by the primary unit. VoIP, IM, P2P, IPsec VPN, HTTPS, SSL VPN, HTTP multiplexing, SSL offloading, WAN optimization, explicit web proxy, and WCCP sessions are also always processed only by the primary unit.

In addition to load balancing, active-active HA also provides device and link failover protection similar to active-passive HA. If the primary unit fails, a subordinate unit becomes the primary unit and resumes operating the cluster. See [“Device failover” on page 1292](#) and [“Link failover \(port monitoring or interface monitoring\)” on page 1319](#) for more information.

Active-active HA provides the same session failover protection as active-passive HA. See [“Session failover \(session pick-up\)” on page 1330](#) for more information about FortiGate session failover and its limitations.

Active-active HA also maintains as many UTM sessions as possible after a failover by continuing to process the UTM sessions that were being processed by the cluster units that are still operating. See [“Active-active HA subordinate units sessions can resume after a failover” on page 1335](#) for more information. Active-passive HA does not support maintaining UTM sessions after a failover.

## Load balancing schedules

The load balancing schedule controls how the primary unit distributes packets to all cluster units. You can select from the following load balancing schedules.

<b>None</b>	No load balancing. Select None when the cluster interfaces are connected to load balancing switches. If you select <i>None</i> , the Primary unit does not load balance traffic and the subordinate units process incoming traffic that does not come from the Primary unit. For all other load balancing schedules, all traffic is received first by the Primary unit, and then forwarded to the subordinate units. The subordinate units only receive and process packets sent from the primary unit.
<b>Hub</b>	Load balancing if the cluster interfaces are connected to a hub. Traffic is distributed to cluster units based on the source IP and destination IP of the packet.
<b>Least-Connection</b>	If the cluster units are connected using switches, select <i>Least Connection</i> to distribute network traffic to the cluster unit currently processing the fewest connections.
<b>Round-Robin</b>	If the cluster units are connected using switches, select Round-Robin to distribute network traffic to the next available cluster unit.
<b>Weighted Round-Robin</b>	Similar to round robin, but weighted values are assigned to each of the units in a cluster based on their capacity and on how many connections they are currently processing. For example, the primary unit should have a lower weighted value because it handles scheduling and forwards traffic. Weighted round robin distributes traffic more evenly because units that are not processing traffic will be more likely to receive new connections than units that are very busy.
<b>Random</b>	If the cluster units are connected using switches, select Random to randomly distribute traffic to cluster units.
<b>IP</b>	Load balancing according to IP address. If the cluster units are connected using switches, select <i>IP</i> to distribute traffic to units in a cluster based on the source IP and destination IP of the packet.
<b>IP Port</b>	Load balancing according to IP address and port. If the cluster units are connected using switches, select IP Port to distribute traffic to units in a cluster based on the source IP, source port, destination IP, and destination port of the packet.

Once a packet has been propagated to a subordinate unit, all packets are part of that same communication session and are also propagated to that same subordinate unit. Traffic is distributed according to communication session, not just according to individual packet.

Any subordinate unit that receives a forwarded packet processes it, without applying load balancing. Note that subordinate units are still considered to be active, because they perform routing, virus scanning, and other FortiGate unit tasks on their share of the traffic. Active subordinate units also share their session and link status information with all cluster units. The only things that active members do not do is make load balancing decisions.

Even though the primary unit is responsible for the load balancing process, the primary unit still acts like a FortiGate unit in that it processes packets, performing, routing, firewall, virus scanning, and other FortiGate unit tasks on its share of the traffic. Depending on the load balancing schedule used, the primary unit may assign itself a smaller share of the total load.

## Selecting which packets are load balanced

The primary unit processes all ICMP traffic. By default, the primary unit also processes all TCP and UDP traffic and load balances virus scanning traffic among all cluster units. You can change the default configuration so that the cluster load balances TCP, UDP traffic, and virus scanning traffic among all cluster units.

Load balancing increases network bandwidth usage and also increases the load on the primary unit CPU. Because of this, in some network environments, load balancing TCP and UDP traffic may not result in an overall cluster performance increase. However, in other network environments, TCP and UDP load balancing may improve cluster performance.

If the cluster is configured to load balance virus scanning sessions, the primary unit uses the load balancing schedule to distribute HTTP, FTP, SMTP, POP3, and IMAP packets to be virus scanned, among the primary unit and the subordinate units. Load balancing virus scanning traffic is much more likely to increase cluster performance. Virus scanning is processor intensive for the cluster unit that is performing the virus scanning. Distributing virus scanning over the cluster units significantly reduces the processing load on the primary unit. As a result overall cluster performance should improve. See [“Load balancing UTM sessions, TCP sessions, and UDP sessions” on page 1347](#).

## More about active-active failover

If a subordinate unit fails, the primary unit re-distributes the connections that the subordinate unit was processing among the remaining active cluster members. If the primary unit fails, the subordinate units negotiate to select a new primary unit. The new primary unit continues to distribute packets among the remaining active cluster units.

Failover works in a similar way if the cluster consists of only two units. If the primary unit fails the subordinate unit negotiates and becomes the new primary unit. If the subordinate unit fails, the primary unit processes all traffic. In both cases, the single remaining unit continues to function as a primary unit, maintaining the HA virtual MAC address for all of its interfaces.

## HTTPS sessions, active-active load balancing, and proxy servers

To prevent HTTPS web filtering problems active-active HA does not load balance HTTPS sessions. The FortiGate unit identifies HTTPS sessions as all sessions received on the HTTPS TCP port. The default HTTPS port is 443. You can use the CLI command `config antivirus service` to configure the FortiGate unit to use a custom port for HTTPS sessions. If you change the HTTPS port using this CLI command, the FGCP stops load balancing all sessions that use the custom HTTPS port.

Normally you would not change the HTTPS port. However, if your network uses a proxy server for HTTPS traffic you may have to use the `config antivirus service` command to configure your cluster to use a custom HTTPS port. If your network uses a proxy server you might also use the same port for both HTTP and HTTPS traffic. In this case you would use `config antivirus service` to configure the FortiGate unit to use custom ports for both HTTP and HTTPS traffic.

Using the same port for HTTP and HTTPS traffic can cause problems with active-active clusters because active-active clusters always load balance HTTP traffic. If both HTTP and HTTPS use the same port, the active-active cluster cannot tell the difference between HTTP and HTTPS traffic and will load balance both HTTP and HTTPS traffic.

As mentioned above, load balancing HTTPS traffic may cause problems with HTTPS web filtering. To avoid this problem, you should configure your proxy server to use different ports for HTTP and HTTPS traffic. Then use the `config antivirus service` command to configure your cluster to also use different ports for HTTP and HTTPS.

## Using FortiGate network processor interfaces to accelerate active-active HA performance

Many FortiGate models and FortiGate AMC modules include network processors that can provide hardware acceleration for active-active HA load balancing by offloading load balancing from the primary unit CPU. HA load balancing can be accelerated by interfaces accelerated by NP network processors.

In some cases, performance of the primary unit can be reduced by active-active HA load balancing. Primary unit CPU cycles and bus bandwidth are required to receive, calculate load balancing schedules, and send balanced packets to the subordinate units. In very busy active-active clusters the primary unit may not be able to keep up with the processing load. This can result in lost traffic and can also cause the primary unit to delay sending heartbeat packets possibly reducing the stability and reliability of the active-active HA cluster.

Adding network processors to busy cluster unit interfaces increases load balancing performance by offloading load balancing to the network processors. The first packet of every new session is received by the primary unit and the primary unit uses its load balancing schedule to select the cluster unit that will process the new session. This information is passed back to the network processor and all subsequent packets of the same sessions are received by the primary unit interface network processor which sends the packet directly to a subordinate unit without using the primary unit CPU. Load balancing is effectively offloaded from the primary unit to the network processor resulting in a faster and more stable active-active cluster.

Using network processors to accelerate load balancing is especially useful if the `load-balance-all` and `load-balance-udp` options are enabled and the cluster is load balancing all TCP and UDP sessions because this could mean that the cluster is load balancing an excessive number of sessions.

To take advantage of network processor load balancing acceleration, connect the cluster unit interfaces with network processors to the busiest networks. Connect non-accelerated interfaces to less busy networks. No special FortiOS or HA configuration is required. Network processor acceleration of active-active HA load balancing is supported for any active-active HA configuration or active-active HA load balancing schedule.

## Configuring load balancing settings

This section describes how to configure the following load balancing settings:

- [Selecting a load balancing schedule](#)
- [Load balancing UTM sessions, TCP sessions, and UDP sessions](#)
- [Configuring weighted-round-robin weights](#)
- [Dynamically optimizing weighted load balancing according to how busy cluster units are](#)

### Selecting a load balancing schedule

You can select the load balancing schedule when initially configuring the cluster and you can change the load balancing schedule at any time while the cluster is operating without affecting cluster operation.

You can select a load balancing schedule from the CLI. Use the following command to select a load balancing schedule:

```
config system ha
    set schedule {hub | ip | ipport | leastconnection | none | random
                | round-robin | weight-round-robin}
end
```

### Load balancing UTM sessions, TCP sessions, and UDP sessions

By default a FortiGate active-active cluster load balances UTM sessions among all cluster units. UTM processing applies protocol recognition, virus scanning, IPS, web filtering, email filtering, data leak prevention (DLP), application control, and VoIP content scanning and protection to HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, NNTP, SIP, SIMPLE, and SCCP sessions accepted by security policies. By load balancing this resource-intensive UTM processing among all cluster units, an active-active HA cluster may provide better UTM performance than a standalone FortiGate unit. Other features enabled in security policies such as Endpoint security, traffic shaping and authentication (identity-based policies) have no effect active-active load balancing.

All other sessions are processed by the primary unit. Using the CLI, you can configure the cluster to load balance TCP sessions among all cluster units in addition to UTM sessions. All UDP, ICMP, multicast, and broadcast sessions are not load balanced, but are processed by the primary unit.

Use the following command to enable load balancing UTM and TCP sessions.

```
config system ha
    set load-balance-all enable
end
```

Enabling `load-balance-all` to load balance TCP sessions may not improve throughput because the cluster requires additional overhead to load balance sessions. The primary unit receives all sessions and load balances some TCP sessions to the subordinate units. Load balancing UTM sessions can improve performance because UTM session performance is limited by CPU performance. However, load balancing a non-UTM session usually requires about as much overhead as just processing it.

If your active-active cluster is processing TCP sessions and not performing UTM, you can enable `load-balance-all` and monitor network performance to see if it improves. If performance is not improved, you should change the HA mode to active-passive since active-active HA is not providing any benefit.

Using the CLI, you can also configure the cluster to load balance UDP sessions among all cluster units in addition to UTM sessions (and optionally TCP sessions).

Use the following command to enable load balancing UTM and UDP sessions.

```
config system ha
    set load-balance-udp enable
end
```

Enabling `load-balance-udp` to load balance UDP sessions may not improve throughput because the cluster requires additional overhead to load balance sessions. The primary unit receives all sessions and load balances some UDP sessions to the subordinate units. Load balancing UTM sessions can improve performance because UTM session performance is limited by CPU performance. However, load balancing a non-UTM session usually requires about as much overhead as just processing it.

If your active-active cluster is processing UDP sessions and not performing UTM, you can enable `load-balance-udp` and monitor network performance to see if it improves. If performance is not improved, you should change the HA mode to active-passive since active-active HA is not providing any benefit.

## Configuring weighted-round-robin weights

You can configure weighted round-robin load balancing for a cluster and configure the static weights for each of the cluster units according to their priority in the cluster. When you set `schedule` to `weight-round-robin` you can use the `weight` option to set the static weight of each cluster unit. The static weight is set according to the priority of each unit in the cluster. A FortiGate HA cluster can contain up to four FortiGate units so you can set up to 4 static weights.

The priority of a cluster unit is determined by its device priority, the number of monitored interfaces that are functioning, its age in the cluster and its serial number. Priorities are used to select a primary unit and to set an order of all of the subordinate units. Thus the priority order of a cluster unit can change depending on configuration settings, link failures and so on. Since weights are also set using this priority order the weights are independent of specific cluster units but do depend on the role of the each unit in the cluster.

You can use the following command to display the priority order of units in a cluster. The following example displays the priority order for a cluster of 5 FortiGate-620B units:

```
get system ha status
Model: 620
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:150 head_office_cla FG600B3908600825 0
Slave :150 head_office_clb FG600B3908600705 1
Slave :150 head_office_clc FG600B3908600702 2
Slave :150 head_office_cld FG600B3908600605 3
Slave :150 head_office_cle FG600B3908600309 4
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
Slave :2 FG600B3908600702
Slave :3 FG600B3908600605
Slave :4 FG600B3908600309
```

The cluster units are listed in priority order starting at the 6th output line. The primary unit always has the highest priority and is listed first followed by the subordinate units in priority order. The last 5 output lines list the cluster units in vcluster 1 and are not always in priority order. For more information about the `get system ha status` command, see [“Viewing cluster status from the CLI” on page 1277](#).

The default static weight for each cluster unit is 40. This means that sessions are distributed evenly among all cluster units. You can use the `weight` option to change the static weights of cluster units to distribute sessions depending on each unit's priority in the cluster. The weight can be between 0 and 255. Increase the weight to increase the number of connections processed by the cluster unit with that priority.

You set the weight for each unit separately. For the example cluster of 5 FortiGate-620B units you can set the weight for each unit as follows:

```
config system ha
set mode a-a
set schedule weight-round-robin
set weight 0 5
set weight 1 10
set weight 2 15
set weight 3 20
set weight 4 30
end
```

If you enter the `get` command to view the HA configuration the output for `weight` would be:

```
weight 5 10 15 20 30 40 40 40 40 40 40 40 40 40 40
```

This configuration has the following results if the output of the `get system ha status` command is that shown above:

- The first five connections are processed by the primary unit (host name head\_office\_cla, priority 0, weight 5). From the output of the
- The next 10 connections are processed by the first subordinate unit (host name head\_office\_clb, priority 1, weight 10)
- The next 15 connections are processed by the second subordinate unit (host name head\_office\_clc, priority 2, weight 15)
- The next 20 connections are processed by the third subordinate unit (host name head\_office\_cld, priority 3, weight 20)
- The next 30 connections are processed by the fourth subordinate unit (host name head\_office\_cle, priority 4, weight 30)

## Dynamically optimizing weighted load balancing according to how busy cluster units are

In conjunction with using static weights to load balance sessions among cluster units you can configure a cluster to dynamically load balance sessions according to individual cluster unit CPU usage, memory usage, and number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions. If any of these system loading indicators increases above configured thresholds, weighted load balancing dynamically sends fewer new sessions to the busy unit until it recovers.

High CPU or memory usage indicates that a unit is under increased load and may not be able to process more sessions. HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy use are also good indicators of how busy a cluster unit is, since processing high numbers of these proxy sessions can quickly reduce overall cluster unit performance.

For example, you can set a CPU usage high watermark threshold. When a cluster unit reaches this high watermark threshold fewer sessions are sent to it. With fewer sessions to process the cluster unit's CPU usage should fall back to the low watermark threshold. When the low watermark threshold is reached the cluster resumes normal load balancing of sessions to the cluster unit.

You can set individual high and low watermark thresholds and weights for CPU usage, memory usage, and for the number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions.

The CPU usage, memory usage, and UTM proxy weights determine how the cluster load balances sessions when a high watermark threshold is reached and also affect how the cluster load balances sessions when multiple cluster units reach different high watermark thresholds at the same time. For example, you might be less concerned about a cluster unit reaching the memory usage high watermark threshold than reaching the CPU usage high watermark threshold. If this is the case you can set the weight lower for memory usage. Then, if one cluster unit reaches the CPU usage high watermark threshold and a second cluster unit reaches the memory usage high watermark threshold the cluster will load balance more sessions to the unit with high memory usage and fewer sessions to the cluster unit with high CPU usage. As a result, reaching the CPU usage high watermark will have a greater affect on how sessions are redistributed than reaching the memory usage high watermark.

When a high watermark threshold is reached, the corresponding weight is subtracted from the static weight of the cluster unit. The lower the weight the fewer the number of sessions that are load balanced to that unit. Subsequently when the low watermark threshold is reached, the static weight of the cluster returns to its configured value. For the weights to all be effective the weights assigned to the load indicators should usually be lower than or equal to the static weights assigned to the cluster units.

Use the following command to set thresholds and weights for CPU and memory usage and HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold <weight> <low> <high>
  set memory-threshold <weight> <low> <high>
  set http-proxy-threshold <weight> <low> <high>
  set ftp-proxy-threshold <weight> <low> <high>
  set imap-proxy-threshold <weight> <low> <high>
  set nntp-proxy-threshold <weight> <low> <high>
  set pop3-proxy-threshold <weight> <low> <high>
  set smtp-proxy-threshold <weight> <low> <high>
end
```

For each option, the weight range is 0 to 255 and the default weight is 5. The low and high watermarks are a percent (0 to 100). The default low and high watermarks are 0 which means they are disabled. The default configuration when weighted load balancing is enabled looks like the following:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold 5 0 0
  set memory-threshold 5 0 0
  set http-proxy-threshold 5 0 0
  set ftp-proxy-threshold 5 0 0
  set imap-proxy-threshold 5 0 0
  set nntp-proxy-threshold 5 0 0
  set pop3-proxy-threshold 5 0 0
  set smtp-proxy-threshold 5 0 0
end
```

When you first enable HA weighted load balancing, the weighted load balancing configuration is synchronized to all cluster units and each cluster unit has the default configuration shown above. Changes to the CPU, memory, HTTP, FTP, IMAP, NNTP, POP3, and SMTP thresholds and low and high watermarks must be made for each cluster unit and are not synchronized to the other cluster units.

---

When you configure them, the high watermarks must be greater than their corresponding low watermarks.

For CPU and memory usage the low and high watermarks are compared with the percentage CPU and memory use of the cluster unit. For each of the UTM proxies the high and low watermarks are compared to a number that represents percent of the max number of proxy sessions being used by a proxy. This number is calculated using the formula:

$$\text{proxy usage} = (\text{current sessions} * 100) / \text{max sessions}$$

where:

`current sessions` is the number of active sessions for the proxy type.

`max sessions` is the session limit for the proxy type. The session limit depends on the FortiGate unit and its configuration.

You can use the following command to display the maximum and current number of sessions for a UTM proxy:

```
get test { ftpd | http | imap | nntp | pop3 | smtp } 4
```

You can use the following command to display the maximum number of sessions and the and current number of sessions for all of the proxies:

```
get test proxyworker 4
```

The command output includes lines similar to the following:

```
get test http 4
HTTP Common
Current Connections          5000/8032
```

In the example, 5000 is the current number of proxy connections being used by HTTP and 8032 is the maximum number of proxy sessions allowed. For this example the proxy usage would be:

```
proxy usage = (5000 * 100) / 8032
proxy usage = 62%
```

### Example weighted load balancing configuration

Consider a cluster of three FortiGate-620B units with host names 620\_ha\_1, 620\_ha\_2, and 620\_ha\_3 as shown in [Figure 215](#). This example describes how to configure weighted load balancing settings for CPU and memory usage for the cluster and then to configure UTM proxy weights to send most HTTP and POP3 proxy sessions to different cluster units.

**Figure 215:**Example HA weighted load balancing configuration

Connect to the cluster CLI and use the following command to set the CPU usage threshold weight to 30, low watermark to 60, and high watermark to 80. This command also sets the memory usage threshold weight to 10, low watermark to 60, and high watermark to 90.

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold 30 60 80
  set memory-threshold 10 60 90
end
```

The static weights for the cluster units remain at the default values of 40. Since this command changes the mode to `a-a` and the schedule to `weight-round-robin` for the first time, the weight settings are synchronized to all cluster units.

As a result of this configuration, if the CPU usage of any cluster unit (for example, `620_ha_1`) reaches 80% the static weight for that cluster unit is reduced from 40 to 10 and only 10 of every 120 new sessions are load balanced to this cluster unit. If the memory usage of `620_ha_1` also reaches 90% the static weight further reduces to 0 and no new sessions are load balanced to `620_ha_1`. Also, if the memory usage of `620_ha_2` reaches 90% the static weight of `620_ha_2` reduces to 30 and 30 of every 120 new sessions are load balanced to `620_ha_2`.

Now that you have established the weight load balancing configuration for the entire cluster you can monitor the cluster to verify that processing gets distributed evenly to all cluster units. From the web-based manager you can go to *System > Config > HA > View HA Statistics* and see the CPU usage, active sessions, memory usage and other statistics for all of the cluster units. If you notice that one cluster unit is more or less busy than others you can adjust the dynamic weights separately for each cluster unit.

For example, in some active-active clusters the primary unit may tend to be busier than other cluster units because in addition to processing sessions the primary unit also receives all packets sent to the cluster and performs load balancing to distribute the sessions to other cluster units. To reduce the load on the primary unit you could reduce the CPU and memory usage high watermark thresholds for the primary unit so that fewer sessions are distributed to the primary unit. You could also reduce the primary unit's high watermark setting for the proxies to distribute more proxy sessions to other cluster units.

Note that this would only be useful if you are using device priorities and override settings to make sure the same unit always becomes the primary unit. See [“Controlling primary unit selection using device priority and override” on page 1140](#).

---

If the example cluster is configured for `620_ha_2` to be the primary unit, connect to the `620_ha_2`'s CLI and enter the following command to set CPU usage, memory usage, and proxy usage high watermark thresholds lower.

```
config system ha
  set cpu-threshold 30 60 70
  set memory-threshold 30 60 70
  set http-proxy-threshold 30 60 70
  set ftp-proxy-threshold 30 60 70
  set imap-proxy-threshold 30 60 70
  set nntp-proxy-threshold 30 60 70
  set pop3-proxy-threshold 30 60 70
  set smtp-proxy-threshold 30 60 70
end
```

As a result, when any of these factors reaches 70% on the primary unit, fewer sessions will be processed by the primary unit, preventing the number of sessions being processed from rising.

## NAT/Route mode active-active cluster packet flow

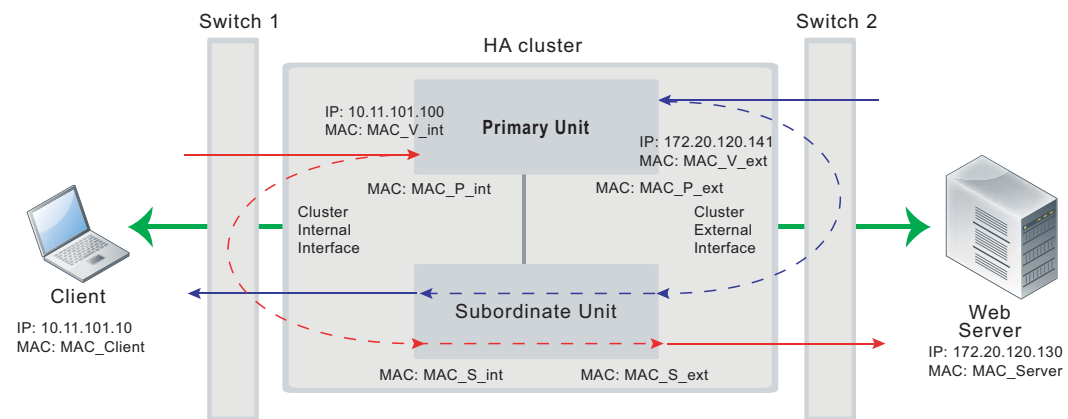

This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in NAT/Route mode. In the example, the NAT/Route mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the Internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In NAT/Route mode, eight MAC addresses are involved in active-active communication between the client and the web server when the primary unit load balances packets to the subordinate unit:

- Internal virtual MAC address (MAC\_V\_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC\_V\_ext) assigned to the primary unit external interface,
- Client MAC address (MAC\_Client),
- Server MAC address (MAC\_Server),
- Primary unit original internal MAC address (MAC\_P\_int),
- Primary unit original external MAC address (MAC\_P\_ext),
- Subordinate unit internal MAC address (MAC\_S\_int),
- Subordinate unit external MAC address (MAC\_S\_ext).

In NAT/Route mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC\_V\_int) and the server only knows the cluster external virtual MAC address (MAC\_V\_ext). The cluster virtual MAC address is described in [“Cluster virtual MAC addresses” on page 1300](#).

**Figure 216:**NAT/Route mode active-active packet flow

### Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC\_V\_int) which corresponds to its IP address of 10.11.101.100.

5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_P_int
Destination	172.20.120.130	MAC_S_int

7. The subordinate unit recognizes that the packet has been forwarded from the primary unit and processes it.
8. The subordinate unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_S_ext
Destination	172.20.120.130	MAC_Server

9. The primary unit forwards further packets in the same session to the subordinate unit.
10. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

### Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC\_V\_ext) which corresponds its IP address of 172.20.120.141.
4. The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_P_ext
Destination	172.20.120.141	MAC_S_ext

6. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
7. The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_S_int
Destination	10.11.101.10	MAC_Client

8. The primary unit forwards further packets in the same session to the subordinate unit.
9. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

## When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails, the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.  
The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.
3. The new primary unit sends gratuitous ARP packets to the 10.10.101.0 network to associate its internal IP address with the internal virtual MAC address.
4. The new primary unit sends gratuitous ARP packets to the 172.20.120.0 network to associate its external IP address with the external virtual MAC address.
5. Traffic sent to the cluster is now received and processed by the new primary unit.  
If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

## Transparent mode active-active cluster packet flow

This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in Transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the Transparent mode cluster.

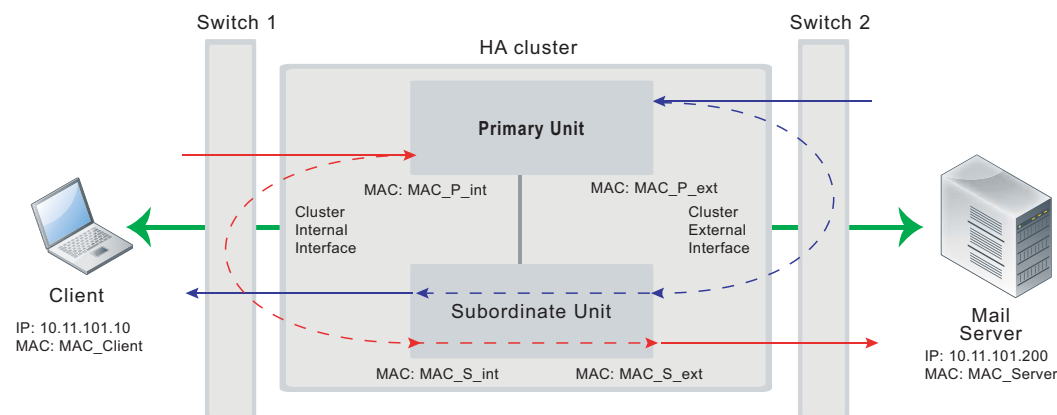

In Transparent mode, six MAC addresses are involved in active-active communication between a client and a server when the primary unit load balances packets to the subordinate unit:

- Client MAC address (MAC\_Client),
- Server MAC address (MAC\_Server),
- Primary unit original internal MAC address (MAC\_P\_int),
- Primary unit original external MAC address (MAC\_P\_ext),
- Subordinate unit internal MAC address (MAC\_S\_int),
- Subordinate unit external MAC address (MAC\_S\_ext).

The HA virtual MAC addresses are not directly involved in communicate between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and load balanced among cluster members.

The cluster's presence on the network and its load balancing are transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the external virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the internal virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

**Figure 217:**Transparent mode active-active packet flow

### Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 10.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC\_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
<b>Source</b>	10.11.101.10	MAC_Client
<b>Destination</b>	10.11.101.200	MAC_Server

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

	IP address	MAC address
<b>Source</b>	10.11.101.10	MAC_P_int
<b>Destination</b>	10.11.101.200	MAC_S_int

7. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
8. The subordinate unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
<b>Source</b>	10.11.101.10	MAC_S_ext
<b>Destination</b>	10.11.101.200	MAC_Server

9. The primary unit forwards further packets in the same session to the subordinate unit.
10. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

### Packet flow from mail server to client

1. To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
2. The primary unit forwards the ARP request to the client computer.
3. The client computer responds with its MAC address (MAC\_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.
4. The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
<b>Source</b>	10.11.101.200	MAC_Server
<b>Destination</b>	10.11.101.10	MAC_Client

5. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
<b>Source</b>	10.11.101.200	MAC_P_ext
<b>Destination</b>	10.11.101.10	MAC_S_ext

6. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.

7. The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_S_int
Destination	10.11.101.10	MAC_Client

8. The primary unit forwards further packets in the same session to the subordinate unit.
9. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

### When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.
3. The new primary unit sends gratuitous ARP requests to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.
4. The new primary unit sends gratuitous ARP requests to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.
5. Traffic sent to the cluster is now received and processed by the new primary unit.  
If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

# HA with FortiGate-VM and third-party products

This chapter provides information about operating FortiOS VM cluster and operating FortiGate clusters with third party products such as layer-2 and layer-3 switches. This chapter describes:

- [FortiGate-VM for VMware HA configuration](#)
- [FortiGate VM for Hyper-V HA configuration](#)
- [Failover issues with layer-3 switches](#)
- [Changing spanning tree protocol settings for some switches](#)
- [Failover and attached network equipment](#)
- [Ethertype conflicts with third-party switches](#)
- [LACP, 802.3ad aggregation and third-party switches](#)

## FortiGate-VM for VMware HA configuration

If you want to combine two or more FortiGate-VM instances into a FortiGate Clustering Protocol (FGCP) High Availability (HA) cluster the VMware server's virtual switches used to connect the heartbeat interfaces must operate in promiscuous mode. This permits HA heartbeat communication between the heartbeat interfaces. HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8890. The FGCP uses link-local IP4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

To enable promiscuous mode in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the Configuration tab in the right pane.
2. In Hardware, select Networking.
3. Select Properties of a virtual switch used to connect heartbeat interfaces.
4. In the Properties window left pane, select vSwitch and then select Edit.
5. Select the Security tab, set Promiscuous Mode to Accept, then select OK.
6. Select Close.

You must also set the virtual switches connected to other FortiGate interfaces to allow MAC address changes and to accept forged transmits. This is required because the FGCP sets virtual MAC addresses for all FortiGate interfaces and the same interfaces on the different VM instances in the cluster will have the same virtual MAC addresses.

To make the required changes in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the Configuration tab in the right pane.
2. In Hardware, select Networking.
3. Select Properties of a virtual switch used to connect FortiGate VM interfaces.
4. Set MAC Address Change to Accept.
5. Set Forged Transmits to Accept.

## FortiGate VM for Hyper-V HA configuration

Promiscuous mode and support for MAC address spoofing is required for FortiGate-VM for Hyper-V to support FortiGate Clustering Protocol (FGCP) high availability (HA). By default the FortiGate-VM for Hyper-V has promiscuous mode enabled in the XML configuration file in the FortiGate-VM Hyper-V image. If you have problems with HA mode, confirm that this is still enabled.

In addition, because the FGCP applies virtual MAC addresses to FortiGate data interfaces and because these virtual MAC addresses mean that matching interfaces of different FortiGate-VM instances will have the same virtual MAC addresses you have to configure Hyper-V to allow MAC spoofing. But you should only enable MAC spoofing for FortiGate-VM data interfaces. You should not enable MAC spoofing for FortiGate HA heartbeat interfaces.

With promiscuous mode enabled and the correct MAC spoofing settings you should be able to configure HA between two or more FortiGate-VM for Hyper-V instances.

## Troubleshooting layer-2 switches

Issues may occur because of the way an HA cluster assigns MAC addresses to the primary unit. Two clusters with the same group ID cannot connect to the same switch and cannot be installed on the same network unless they are separated by a router.

### Forwarding delay on layer 2 switches

You must ensure that if there is a switch between the FortiGate HA cluster and the network its is protecting and the switch has a forwarding delay (even if spanning tree is disabled) when one of its interfaces is activated then the forwarding delay should be set as low as possible. For example, some versions of Cisco IOS have a forwarding delay of 15 seconds even when spanning tree is disabled. If left at this default value then TCP session pickup can fail because traffic is not forwarded through the switch on HA failover.

## Failover issues with layer-3 switches

After a failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables of the switches connected to the cluster. If the cluster is connected using layer-2 switches, the MAC forwarding tables (also called arp tables) are refreshed by the gratuitous ARP packets and the switches start directing packets to the new primary unit.

In some configurations that use layer-3 switches, after a failover, the layer-3 switches may not successfully re-direct traffic to the new primary unit. The possible reason for this is that the layer-3 switch might keep a table of IP addresses and interfaces and may not update this table for a relatively long time after the failover (the table is not updated by the gratuitous ARP packets). Until the table is updated, the layer-3 switch keeps forwarding packets to the now failed cluster unit. As a result, traffic stops and the cluster does not function.

As of the release date of this document, Fortinet has not developed a workaround for this problem. One possible solution would be to clear the forwarding table on the layer-3 switch.

The `config system ha link-failed-signal` command described in [“Updating MAC forwarding tables when a link failover occurs” on page 1323](#) can be used to resolve link failover issues similar to those described here.

## Changing spanning tree protocol settings for some switches

Configuration changes may be required when you are running an active-active HA cluster that is connected to a switch that operates using the spanning tree protocol. For example, the following spanning tree parameters may need to be changed:

<b>Maximum Age</b>	The time that a bridge stores the spanning tree bridge control data unit (BPDU) before discarding it. A maximum age of 20 seconds means it may take 20 seconds before the switch changes a port to the listening state.
<b>Forward Delay</b>	The time that a connected port stays in listening and learning state. A forward delay of 15 seconds assumes a maximum network size of seven bridge hops, a maximum of three lost BPDUs and a hello-interval of 2 seconds.

For an active-active HA cluster to be compatible with the spanning tree algorithm, the FGCP requires that the sum of maximum age and forward delay should be less than 20 seconds. The maximum age and forward delay settings are designed to prevent layer 2 loops. If there is no possibility of layer 2 loops in the network, you could reduce the forward delay to the minimum value.

For some Dell 3348 switches the default maximum age is 20 seconds and the default forward delay is 15 seconds. In this configuration the switch cannot work with a FortiGate HA cluster. However, the switch and cluster are compatible if the maximum age is reduced to 10 seconds and the forward delay is reduced to 5 seconds.

## Spanning Tree protocol (STP)

Spanning tree protocol is an IEEE 802.1 standard link management protocol that for media access control bridges. STP uses the spanning tree algorithm to provide path redundancy while preventing undesirable loops in a network that are created by multiple active paths between stations. Loops can be created if there are more than route between two hosts. To control path redundancy, STP creates a tree that spans all of the switches in an extended network. Using the information in the tree, the STP can force redundant paths into a standby, or blocked, state. The result is that only one active path is available at a time between any two network devices (preventing looping). Redundant links are used as backups if the initial link should fail. Without spanning tree in place, it is possible that two connections may be simultaneously live, which could result in an endless loop of traffic on the network.

## Bridge Protocol Data Unit (BPDU)

BPDUs are spanning tree data messages exchanged across switches within an extended network. BPDU packets contain information on ports, addresses, priorities and costs and ensure that the data ends up where it was intended to go. BPDU messages are exchanged across bridges to detect loops in a network topology. The loops are then removed by shutting down selected bridge interfaces and placing redundant switch ports in a backup, or blocked, state.

## Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize

and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

## Ethertype conflicts with third-party switches

Some third-party network equipment may use packets with Ethertypes that are the same as the ethertypes used for HA heartbeat packets. For example, Cisco N5K/Nexus switches use Ethertype 0x8890 for some functions. When one of these switches receives Ethertype 0x8890 heartbeat packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGate units connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8893, and 0x8891 to pass.

You can also use the following CLI commands to change the Ethertypes of the HA heartbeat packets:

```
config system ha
    set ha-eth-type <ha_ethertype_4-digit_hex>
    set hc-eth-type <hc_ethertype_4-digit_hex>
    set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For more information, see [“Heartbeat packet Ethertypes” on page 1297](#).

## LACP, 802.3ad aggregation and third-party switches

If a cluster contains 802.3ad aggregated interfaces you should connect the cluster to switches that support configuring multiple Link Aggregation (LAG) groups.

The primary and subordinate unit interfaces have the same MAC address, so if you cannot configure multiple LAG groups a switch may place all interfaces with the same MAC address into the same LAG group; disrupting the operation of the cluster.

You can change the FortiGate configuration to prevent subordinate units from participating in LACP negotiation. For example, use the following command to do this for an aggregate interface named Port1\_Port2:

```
config system interface
    edit Port1_Port2
        set lacp-ha-slave disable
    end
```

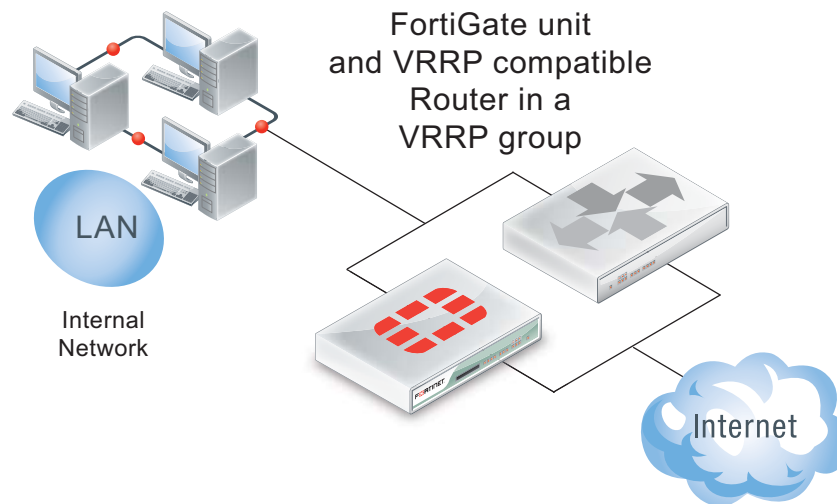

This configuration prevents the subordinate unit interfaces from sending or receiving packets. Resulting in the cluster not being able to operate in active-active mode. As well, failover may be slower because after a failover the new primary unit has to perform LACP negotiation before being able to process network traffic.

For more information, see [“Example: HA and 802.3ad aggregated interfaces” on page 1188](#).

# VRRP

A Virtual Router Redundancy Protocol (VRRP) configuration can be used as a high availability solution to make sure that a network maintains connectivity with the Internet (or with other networks) even if the default router for the network fails. Using VRRP, if a router or a FortiGate unit fails all traffic to this router transparently fails over to another router or FortiGate unit that takes over the role of the router or FortiGate unit that failed. If the failed router or FortiGate unit is restored, it will once again take over processing traffic for the network. VRRP is described by [RFC 3768](#).

**Figure 218:**Example VRRP configuration

To configure VRRP you create a VRRP group that contains two or more routers. Some or all of these routers can be FortiGate units. You can include different FortiGate models in the same VRRP group. The group members are configured to be the master router and one or more backup routers of the VRRP group. The network directs all traffic to the master's IP address and MAC address. If the master fails, VRRP dynamically shifts packet forwarding to a backup router. VRRP provides this redundancy without user intervention or additional configuration to any of the devices on the network.

The VRRP redundancy scheme means that devices on the network keep a single IP address for the default gateway and this IP address maps to a well-known virtual MAC address. If the VRRP master fails, one of the backup units becomes the new master and acquires virtual IP and MAC addresses that match the addresses of the master. The network then automatically directs all traffic to the backup unit. VRRP uses the broadcast capabilities of Ethernet networks. As long as one of the routers in a VRRP group is running, ARP requests for the default gateway IP address always receive replies. Additionally, hosts can send packets outside their subnet without interruption.

FortiGate units support VRRP and can be quickly and easily integrated into a network that has already deployed a group of routers using VRRP. You can also create a new VRRP configuration consisting of a FortiGate unit acting as a VRRP master with one or more VRRP-compatible routers acting as backup routers. Some or all of those backup routers can be FortiGate units.

During normal operation the VRRP master unit sends VRRP advertisement messages to the backup units. A backup unit will not attempt to become a master unit while it is receiving these messages. When a FortiGate unit operating as a VRRP master fails, a backup unit takes its place and continues processing network traffic. The backup unit assumes the master unit has

failed if it stops receiving the advertisement messages from the master unit. The backup unit with the highest priority becomes the new master unit after a short delay. During this delay the new master unit sends gratuitous ARPs to the network to map the virtual router IP address to its MAC address. As a result, all packets sent to the default route IP address are sent to the new master unit. If the backup unit is a FortiGate unit, the network continues to benefit from FortiOS security features. If the backup unit is a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate unit is back on line.

During a VRRP failover, as the backup unit starts to forward traffic it will not have session information for all of the failed over in-progress sessions. If the backup unit is operating as a normal FortiGate unit it will not be able to forward this traffic because of the lack of session information. To resolve this problem, immediately after a failover and for a short time as it is taking over traffic processing, the backup unit operates with asymmetric routing enabled. This allows the backup unit to re-create all of the in-progress sessions and add them to the session table. While operating with asymmetric routing enabled, the backup unit cannot apply security functions. When the start-time ends the backup unit disables asymmetric routing and returns to normal operation including applying security functions.

## Adding a VRRP virtual router to a FortiGate interface

Use the following command to add a VRRP virtual router to the port10 interface of a FortiGate unit. This VRRP virtual router has a virtual router ID of 200, uses IP address 10.31.101.200 and has a priority of 255. Since this is the highest priority this interface is configured to be the master of the VRRP group with ID number 200.

```
config system interface
  edit port10
    config vrrp
      edit 200
        set vrip 10.31.101.200
        set priority 255
      end
    end
  end
```

## VRRP virtual MAC address

The VRRP virtual MAC address (or virtual router MAC address) is a shared MAC address adopted by the VRRP master. If the master fails the same virtual MAC master fails over to the new master. As a result, all packets for VRRP routers can continue to use the same virtual MAC address. You must enable the VRRP virtual MAC address feature on all members of a VRRP group.

Each VRRP router is associated with its own virtual MAC address. The last part of the virtual MAC depends on the VRRP virtual router ID using the following format:

00-00-5E-00-01-<VRID\_hex>

Where <VRID\_hex> is the VRRP virtual router ID in hexadecimal format in internet standard bit-order. For more information about the format of the virtual MAC see RFC 3768.

Some examples:

- If the VRRP virtual router ID is 10 the virtual MAC would be 00-00-5E-00-01-0a.
- If the VRRP virtual router ID is 200 the virtual MAC would be 00-00-5E-00-01-c8.

The VRRP virtual MAC address feature is disabled by default. When you enable the feature on a FortiGate interface, all of the VRRP routers added to that interface use their own VRRP virtual MAC address. Each virtual MAC address will be different because each virtual router has its own ID.

Use the following command to enable the VRRP virtual MAC address on the port2 interface:

```
config system interface
    edit port2
        set vrrp-virtual-mac enable
    end
end
```

The port2 interface will now accept packets sent to the MAC addresses of the VRRP virtual routers added to this interface.

Using the VRRP virtual MAC address can improve network efficiency especially on large and complex LANs because when a failover occurs devices on the LAN do not have to learn a new MAC address for the new VRRP router.

If the VRRP virtual MAC address feature is disabled, the VRRP group uses the MAC address of the master. In the case of a FortiGate VRRP virtual router this is the MAC address of the FortiGate interface that the VRRP virtual routers are added to. If a master fails, when the new master takes over it sends gratuitous ARPs to associate the VRRP virtual router IP address with the MAC address of the new master (or the interface of the FortiGate unit that has become the new master). If the VRRP virtual MAC address is enabled the new master uses the same MAC address as the old master.

## Configuring VRRP

To configure VRRP you must configure two or more FortiGate interfaces or routers with the same virtual router ID and IP address. Then these FortiGate units or routers can automatically join the same VRRP group. You must also assign priorities to each of the FortiGate units or routers in the VRRP group. One of the FortiGate units or routers must have the highest priority to become the master. The other FortiGate units or routers in the group are assigned lower priorities and become backup units. All of the units in the VRRP group should have different priorities. If the master unit fails, VRRP automatically fails over to the remaining unit in the group with the highest priority.

You configure VRRP from the FortiGate CLI by adding a VRRP virtual router to a FortiGate interface. You can add VRRP virtual routers to multiple FortiGate interfaces and you can add more than one virtual router to the same interface.

### Example VRRP configuration: two FortiGate units in a VRRP group

This example includes a VRRP group consisting of two FortiGate units that connect an internal network to the Internet. As shown in [Figure 219](#), the internal network's default route is 10.31.101.120.

The FortiGate port2 interfaces connect to the internal network. A VRRP virtual router is added to each FortiGate unit's port2 interface. The virtual router IP address is 10.31.101.120 (the internal network's default route) and the virtual router's ID is 5. The VRRP priority of the master unit is set to 255 and the VRRP priority of the backup unit is 50. The port2 interface of each FortiGate unit should have an IP address that is different from the virtual router IP address and the port2 interface IP addresses should be different from each other.

This example also includes enabling the VRRP virtual MAC address on both FortiGate unit port2 interfaces so that the VRRP group uses the VRRP virtual MAC address.

**Figure 219:**Example VRRP configuration with two FortiGate units

### To configure the FortiGate units for VRRP

1. Select one of the FortiGate units to be the VRRP master and the other to be the backup unit.
2. From the master unit's CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
    edit port2
        set vrrp-virtual-mac enable
    config vrrp
        edit 5
            set vrip 10.31.101.120
            set priority 255
        end
    end
```

3. From the backup unit's CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
    edit port2
        set vrrp-virtual-mac enable
    config vrrp
        edit 5
            set vrip 10.31.101.120
            set priority 50
        end
    end
```

### Example VRRP configuration: VRRP load balancing two FortiGate units and two VRRP groups

In this configuration two VRRP groups are involved. Each FortiGate unit participates in both of them. One FortiGate unit is the master of one group and the other FortiGate unit is the master of the other group. The network distributes traffic between two different default routes (10.31.101.120 and 10.31.101.130). One VRRP group is configured with one of the default route IP addresses and the other VRRP group get the other default route IP address. So during

normal operation both FortiGate units are processing traffic and the VRRP groups are used to load balance the traffic between the two FortiGate units.

If one of the FortiGate units fails, the remaining FortiGate unit becomes the master of both VRRP groups. The network sends all traffic for both default routes to this FortiGate unit. The result is a configuration that under normal operation load balances traffic between two FortiGate units, but if one of the FortiGate units fails, all traffic fails over to the unit that is still operating.

This example also includes enabling the VRRP virtual MAC address on both FortiGate unit port2 interfaces so that the VRRP groups use their VRRP virtual MAC addresses.

**Figure 220:**Example VRRP configuration with two FortiGate units and two VRRP groups

### To configure the FortiGate units

1. Log into the CLI of FortiGate unit A.
2. Enter the following command to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate unit A:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
  config vrrp
    edit 50 (32)
      set vrip 10.31.101.120
      set priority 255
    next
    edit 100 (64)
      set vrip 10.31.101.130
      set priority 50
    end
  end
end
```

3. Log into the CLI of FortiGate unit B.

4. Enter the following command to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate unit B:

```
config system interface
    edit port2
        set vrrp-virtual-mac enable
    config vrrp
        edit 50
            set vrip 10.31.101.120
            set priority 50
        next
        edit 100
            set vrip 10.31.101.130
            set priority 255
        end
    end
end
```

## Optional VRRP configuration settings

In addition to the basic configuration settings, you can change to the VRRP configuration to:

- Adjust the virtual router advertisement message interval between 1 and 255 seconds using the `adv-interval` option.
- Adjust the startup time using the `start-time` option. The default start time is 3 seconds and the range is 1 to 255 seconds. The start time is the maximum time that the backup unit waits between receiving advertisement messages from the master unit. If the backup unit does not receive an advertisement message during this time it assumes the master has failed and becomes the new master unit. In some cases the advertisement messages may be delayed. For example, some switches with spanning tree enabled may delay some of the advertisement message packets. If you find that backup units are attempting to become master units without the master unit failing, you can extend the start time to make sure the backup units wait long enough for the advertisement messages.
- Enable or disable individual virtual router configurations using the `status` option. Normally virtual router configurations are enabled but you can temporarily disable one if its not required.
- Enable or disable preempt mode using the `preempt` option. In preempt mode a higher priority backup unit can preempt a lower priority master unit. This can happen if a master has failed, a backup unit has become the master unit, and the failed master is restarted. Since the restarted unit will have a higher priority, if preempt mode is enabled the restarted unit will replace the current master unit. Preempt mode is enabled by default.
- Monitor the route to a destination IP address using the `vrdst` option.

# FortiGate Session Life Support Protocol (FGSP)

You can use the `config system session-sync` command to configure the FortiGate Session Life Support Protocol (FGSP) (previously called TCP session synchronization or standalone session synchronization) between two FortiGate units. The two FortiGate units must be the same model. The FGSP synchronizes both IPv4 and IPv6 TCP, UDP, ICMP, expectation, and NAT sessions. You can use this feature with external routers or load balancers configured to distribute or load balance sessions between two peer FortiGate units. If one of the peers fails, session failover occurs and active sessions fail over to the peer that is still operating. This failover occurs without any loss of data. As well, the external routers or load balancers will detect the failover and re-distribute all sessions to the peer that is still operating.

In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. However, the FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions.

You cannot configure FGSP HA when FGCP HA is enabled. However FCSP HA is compatible with VRRP.

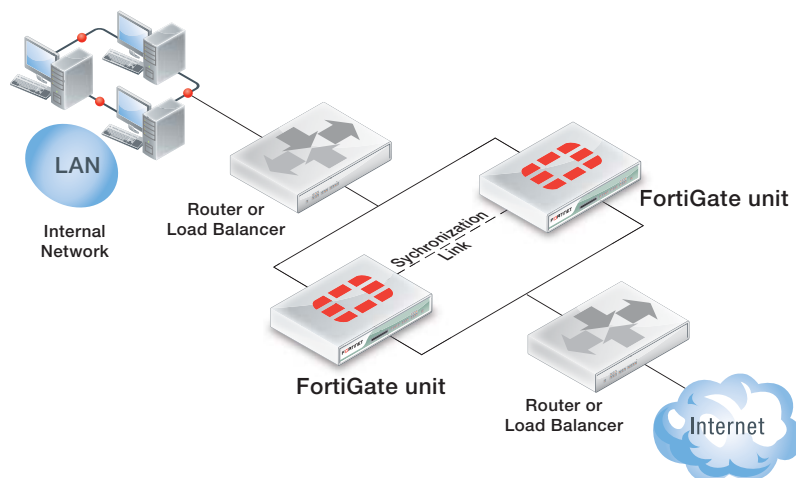

FCSP or standalone session synchronization is not supported if the FortiGate units are running different firmware versions.

---

The FGSP can be used instead of FGCP HA to provide **session synchronization** between two peer FortiGate units. If the external load balancers direct all sessions to one peer the affect is similar to active-passive FGCP HA. If external load balancers or routers load balance traffic to both peers, the effect is similar to active-active FGCP HA. The load balancers should be configured so that all of the packets for any given session are processed by the same peer. This includes return packets.

**Figure 221:FGSP HA**

By default, FGSP synchronizes all IPv4 and IPv6 TCP sessions and also synchronizes the configuration of the FortiGate units.

You can optionally enable session pickup to synchronize connectionless (UDP and ICMP) sessions, expectation sessions, and NAT sessions. If you do not enable session pickup, the FGSP does not share session tables for the particular session type and sessions do not resume after a failover. All sessions that are interrupted by the failover and must be re-established at the application level. Many protocols can successfully restart sessions with little, or no, loss of data. Others may not recover easily. Enable session pickup for sessions that may be difficult to reestablish. Since session pickup requires FortiGate resources, only enable this feature for sessions that you need to have synchronized.

You can also optionally add filters to control which sessions are synchronized. You can add filters to only synchronize packets from specified source and destination addresses, specified source and destination interfaces, and specified services.

Load balancing and session failover is done by external routers or load balancers instead of by the FGSP. The FortiGate units just perform session synchronization to support session failover.

## Synchronizing the configuration

The FGSP also includes configuration synchronization, allowing you to make configuration changes once for both FortiGate units instead of requiring you to make duplicate configuration changes on each FortiGate unit. Settings that identify the FortiGate unit to the network, for example, interface IP addresses and BGP neighbor settings, are not synchronized so each FortiGate unit maintains its identity on the network.

By default configuration synchronization is disabled. You can use the following command to enable it.

```
config system ha
    set standalone-config-sync enable
end
```

## Synchronizing UDP and ICMP (connectionless) sessions

In many configurations, due to their non-stateful nature, UDP and ICMP sessions don't need to be synchronized to naturally failover. However, if its required you can configure the FGSP to synchronize UDP and ICMP sessions by entering the following command:

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

## Synchronizing NAT sessions

By default, NAT session are not synchronized. However, the FGSP can synchronize NAT session if you enter the following command:

```
config system ha
    set session-pickup enable
    set session-pickup-nat enable
end
```

However, if you want NAT sessions to resume after a failover you should not configure NAT to use the destination interface IP address since the FGSP FortiGate units have different IP addresses. With this configuration, after a failover all sessions that include the IP addresses of interfaces on the failed FortiGate unit will have nowhere to go since the IP addresses of the failed FortiGate unit will no longer be on the network.

Instead, in an FGSP configuration, if you want NAT sessions to failover you should use IP pools with the type set to overload (which is the default IP pool type). For example:

```
config firewall ippool
    edit FGSP-pool
        set type overload
        set startip 172.20.120.10
        set endip 172.20.120.20
    end
```

Then when you configure NAT firewall policies, turn on NAT and select to use dynamic IP pool and select the IP Pool that you added. Add the same IP pools and firewall policies to both FortiGate units.

## Synchronizing expectation (asymmetric) sessions

By default, expectation sessions (or asymmetric sessions) are not synchronized. Normally, session synchronization cannot be asymmetric because it is stateful. So all of the packets of a given session must be processed on the same peer. This includes return packets.

However, if you have an asymmetric routing configuration, you can enter the following command to synchronize asymmetric sessions by dynamically detecting asymmetric sessions and disabling anti-reply for these sessions.

```
config system ha
    set session-pickup enable
    set session-pickup-expectation enable
end
```

The FGSP enforces firewall policies for asymmetric traffic, including cases where the TCP 3-way handshake is split between two FortiGates. For example, FGT-A receives the TCP-SYN, FGT-B receives the TCP-SYN-ACK, and FGT-A receives the TCP-ACK. Under normal conditions a firewall will drop this connection since the 3-way handshake was not seen by the same firewall. However two FortiGates with FGSP configured will be able to properly pass this traffic since the firewall sessions are synchronized.

If traffic will be highly asymmetric, as described above, the following command must be enabled on both FortiGates.

```
config system ha
    set session-pickup enable
    set session-pickup-expectation enable
end
```

This asymmetric function can also work with connectionless UDP and ICMP traffic. The following command needs to be enabled on both FortiGates.

```
config system ha
    set session-pickup enable
    set session-pickup-connectionless enable
end
```

Synchronizing asymmetric traffic can be very useful in situations where multiple Internet connections from different ISPs are spread across two FortiGates. Since it is typically not possible to guarantee Internet bound traffic leaving via an ISP will return using the exact same ISP, the FGSP provides critical firewall functions in this situation.

The FGSP also has applications in virtualized computing environments where virtualized hosts move between data centers. The firewall session synchronization features of FGSP allow for more flexibility than in traditional firewalling functions.

## UTM Flow-based Inspection and Asymmetric Traffic

UTM inspection (flow or proxy based) for a session is not expected to work properly if the traffic in the session is balanced across more than one FortiGate in either direction. Flow-based UTM should be used in FGSP deployments.

For an environment where traffic is symmetric, UTM can be used with the following limitations:

- No session synchronization for the sessions inspected using proxy-based UTM. Sessions will drop and need to be reestablished after data path failover.
- Sessions with flow-based UTM will failover; however, inspection of failed over sessions after the failover may not work.

A single FortiGate must see both the request and reply traffic for UTM inspection to function correctly. For environments where asymmetric traffic is expected, UTM inspection should not be used.

## Notes and limitations

FGSP HA has the following limitations:

- The FGSP is a global configuration option. As a result you can only add one service to a filter configuration. You cannot add custom services or service groups even if virtual domains are not enabled.

- You can only add one filter configuration to a given FGSP configuration. However, you can add multiple filters by adding multiple identical FGSP configurations, each one with a different filter configuration.
- Sessions accepted by security policies with UTM options configured are not synchronized.
- FGSP HA is configured from the CLI.
- FGSP HA is available for FortiGate units or virtual domains operating in NAT/Route or Transparent mode. NAT sessions are not synchronized in either mode (unless NAT synchronization is enabled as described in [“Synchronizing NAT sessions” on page 1372](#)). In NAT/Route mode, only sessions for route mode security policies are synchronized. In Transparent mode, only sessions for normal Transparent mode policies are synchronized.
- FGSP HA is supported for traffic on physical interfaces, VLAN interfaces, zones, aggregate interfaces, and NPx (NP4, NP6 etc.) accelerated interfaces. The FGSP has not been tested for inter-vdom links, between HA clusters, and for redundant interfaces.
- The names of the matching interfaces, including VLAN interfaces, aggregate interfaces and so on, must be the same on both peers.

## Configuring FGSP HA

You configure FGSP HA separately for each virtual domain to be synchronized. If virtual domain configuration is not enabled, you configure FGSP HA for the root virtual domain. When virtual domain configuration is enabled and you have added virtual domains you configure FGSP HA for each virtual domain to be synchronized. You don't have to synchronize all virtual domains.

You must configure FGSP HA and network settings on both peers. Once you establish the initial configuration, the configurations of both FortiGate units are synchronized so when you change the configuration of one, the changes are synchronized to the other.

On each FortiGate unit, configuring FGSP HA consists of selecting the virtual domains to be synchronized using the `syncvd` field, selecting the virtual domain on the other peer that receives the synchronization packets using the `peervd` field, and setting the IP address of the interface in the peer unit that receives the synchronization packets using the `peerip` field. The interface with the `peerip` must be in the `peervd` virtual domain.

The `syncvd` and `peervd` settings must be the same on both peers. However, the `peerip` settings will be different because the `peerip` setting on the first peer includes the IP address of an interface on the second peer. And the `peerip` setting on the second peer includes the IP address of an interface on the first peer.

For FGSP HA to work properly all synchronized virtual domains must be added to both peers. The names of the matching interfaces in each virtual domain must also be the same; this includes the names of matching VLAN interfaces. Note that the index numbers of the matching interfaces and VLAN interfaces can be different. Also the VLAN IDs of the matching VLAN interfaces can be different.

For a configuration example, see [“Basic example configuration” on page 1375](#).

## Configuring the session synchronization link

When FGSP HA is operating, the peers share session information over an Ethernet link between the peers similar to an HA heartbeat link. Usually you would use the same interface on each peer for session synchronization. You should connect the session synchronization interfaces directly without using a switch or other networking equipment. For FortiGate-5000 systems you can use a backplane interface as the session synchronization link.

You can use different interfaces on each peer for session synchronization links. Also, if you have multiple sessions synchronization configurations, you can have multiple links between the peers. In fact if you are synchronizing a lot of sessions, you may want to configure and connect multiple session synchronization links to distribute session synchronization traffic to these multiple links.

You cannot configure backup session synchronization links. Each configuration only includes one session synchronization link.

The session synchronization link should always be maintained. If session synchronization communication is interrupted and a failure occurs, sessions will not failover and data could be lost.

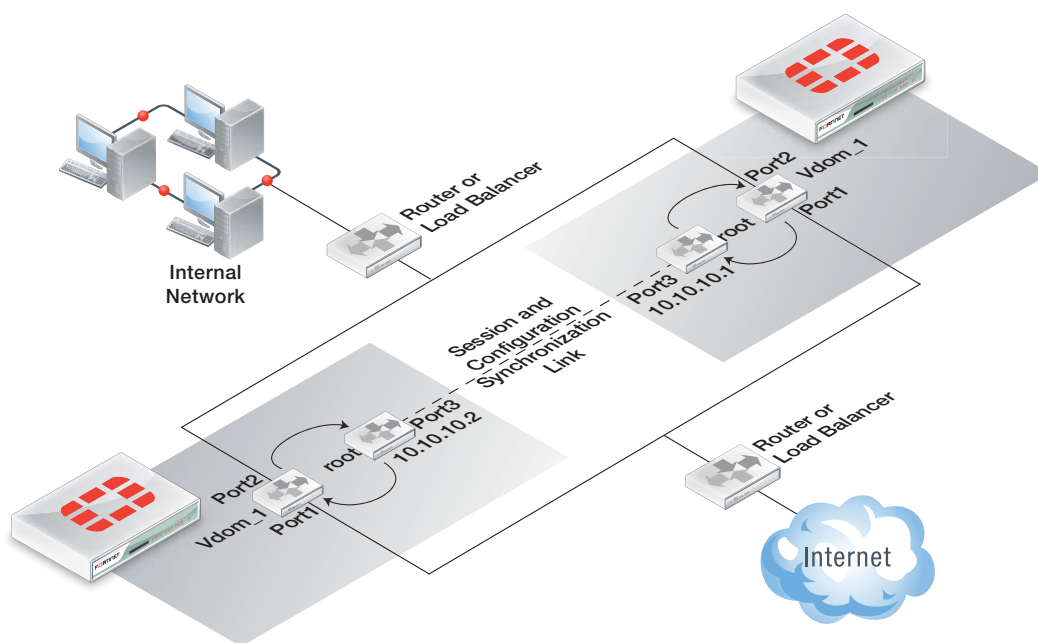

Session synchronization traffic can use a considerable amount of network bandwidth. If possible, session synchronization link interfaces should only be used for session synchronization traffic and not for data traffic.

## Basic example configuration

The following configuration example shows how to configure basic FGSP HA for the two peer FortiGate units shown in [Figure 222 on page 1375](#). The host names of peers are peer\_1 and peer\_2. Both peers are configured with two virtual domains: root and vdom\_1. All sessions processed by vdom\_1 are synchronized. The synchronization link interface is port3 which is in the root virtual domain. The IP address of port3 on peer\_1 is 10.10.10.1. The IP address of port3 on peer\_2 is 10.10.10.2.

Also on both peers, port1 and port2 are added to vdom\_1. On peer\_1 the IP address of port1 is set to 192.168.20.1 and the IP address of port2 is set to 172.110.20.1. On peer\_2 the IP address of port1 is set to 192.168.20.2 and the IP address of port2 is set to 172.110.20.2.

**Figure 222:**Example FGSP HA network configuration

### To configure FGSP HA

1. Configure the load balancer or router to send all sessions to peer\_1.
2. Configure the load balancer or router to send all traffic to peer\_2 if peer\_1 fails.

3. Use normal FortiGate configuration steps on peer\_1:
  - Enable virtual domain configuration.
  - Add the vdom\_1 virtual domain.
  - Add port1 and port2 to the vdom\_1 virtual domain and configure these interfaces.
  - Set the IP address of port1 to 192.168.20.1.
  - Set the IP address of port2 to 172.110.20.1.
  - Set the IP address of port3 to 10.10.10.1.
  - Add route mode security policies between port1 and port2 to vdom\_1.
4. Enter the following commands to configure session synchronization for peer\_1

```
config system session-sync
  edit 1
    set peerip 10.10.10.2
    set peervd root
    set syncvd vdom_1
  end
```

- 5 Use normal FortiGate configuration steps on peer\_2:
  - Enable virtual domain configuration.
  - Add the vdom\_1 virtual domain.
  - Add port1 and port2 to the vdom\_1 virtual domain and configure these interfaces.
  - Set the IP address of port1 to 192.168.20.2.
  - Set the IP address of port2 to 172.110.20.2.
  - Set the IP address of port3 to 10.10.10.1.
  - Add route mode security policies between port1 and port2 to vdom\_1.
6. Enter the following command to configure session synchronization for peer\_1

```
config system session-sync
  edit 1
    set peerip 10.10.10.1
    set peervd root
    set syncvd vdom_1
  end
```

Now that the FortiGate units are connected and configured their configurations are synchronized, so when you make a configuration change on one FortiGate unit it is synchronized to the other one.

### To add filters

You can add a filter to this basic configuration if you only want to synchronize some TCP sessions. For example you can enter the following command to add a filter so that only HTTP sessions are synchronized:

```
config system session-sync
  edit 1
    config filter
      set service HTTP
    end
  end
```

You can also add a filter to control the source and destination addresses of the IPv4 packets that are synchronized. For example you can enter the following command to add a filter so that only sessions with source addresses in the range 10.10.10.100 to 10.10.10.200 are synchronized.

```
config system session-sync
  edit 1
    config filter
      set srcaddr 10.10.10.100 10.10.10.200
    end
  end
```

You can also add a filter to control the source and destination addresses of the IPv6 packets that are synchronized. For example you can enter the following command to add a filter so that only sessions with destination addresses in the range 2001:db8:0:2::/64 are synchronized.

```
config system session-sync
  edit 1
    config filter
      set dstaddr6 2001:db8:0:2::/64
    end
  end
```

### **To synchronize UDP and ICMP sessions**

You enter the following command to add synchronization of UDP and ICMP sessions to this configuration:

```
config system ha
  set session-pickup enable
  set session-pickup-connectionless enable
end
```

### **To synchronize the configuration**

Enter the following command to enable configuration synchronization.

```
config system ha
  set standalone-config-sync enable
end
```

## **Verifying FGSP configuration and synchronization**

You can use the following diagnose commands to verify that the FGSP and its synchronization functions are operating correctly.

## FGSP configuration summary and status

Enter the following command to display a summary of the FGSP configuration and synchronization status:

```
diagnose sys session sync
sync_ctx: sync_started=1, sync_tcp=1, sync_others=1,
sync_expectation=1, sync_redir=0, sync_nat=1.
sync: create=12:0, update=0, delete=0:0, query=14
recv: create=14:0, update=0, delete=0:0, query=12
ses pkts: send=0, alloc_fail=0, recv=0, recv_err=0 sz_err=0
nCfgr_sess_sync_num=5, mtu=16000
sync_filter:
1: vd=0, szone=0, dzone=0, saddr=0.0.0.0:0.0.0.0,
    daddr=0.0.0.0:0.0.0.0,
```

`sync_started=1` shows that synchronization is working. If this is set to 0 then something is not correct with session synchronization and synchronization has not been able to start because of it.

`sync_tcp=1`, `sync_others=1`, `sync_expectation=1`, and `sync_nat=1` show that the FGSP has been configured to synchronize TCP, connectionless, asymmetric, and NAT sessions.

`sync: create=12:0` and `recv: create=14:0` show that this FortiGate has synchronized 12 sessions to its peer and has received 14 sessions from its peer.

`sync_filter` shows the configured FGSP filter. In this case no filter has been created so all sessions are synchronized.

`vd=0` indicates that root VDOM sessions are synchronized.

## Verifying that sessions are synchronized

Enter the command `diagnose sys session list` to display information about the sessions being processed by the FortiGate. In the command output look for sessions that should be synchronized and make sure they contain output lines that include `syncd` (for example, `state=log may_dirty ndr syncd`) to confirm that they are being synchronized by the FGSP.

```
diagnose sys session list
session info: proto=6 proto_state=05 duration=469 expire=0 timeout=3600
flags=00000000 sockflag=00000000 sockport=21 av_idx=0 use=4
origin-shaper=
reply-shaper=
per_ip_shaper=
ha_id=0 policy_dir=0 tunnel=/
state=log may_dirty ndr syncd
statistic(bytes/packets/allow_err): org=544/9/1 reply=621/7/0 tuples=2
origin->sink: org pre->post, reply pre->post
      dev=46->45/45->46
gwy=10.2.2.1/10.1.1.1
hook=pre dir=org act=noop
      192.168.1.50:45327->172.16.1.100:21(0.0.0.0:0)
hook=post dir=reply act=noop
      172.16.1.100:21->192.168.1.50:45327(0.0.0.0:0)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=1 id_policy_id=0 auth_info=0 chk_client_info=0 vd=0
serial=00002deb tos=ff/ff ips_view=1 app_list=2000 app=16427
dd_type=0 dd_mode=0
per_ip_bandwidth meter: addr=192.168.1.50, bps=633
```

# Configuring FRUP

The FortiGate Redundant UTM Protocol (FRUP) provides similar redundancy to FGCP full mesh HA in a single unified design that includes redundant switching and routing. FRUP is available on the FortiGate-100D and will be expanded to other models in future releases.

A FRUP cluster consists of 2 (and only 2) identical FortiGate-100D units that have dual redundant links to all connected devices and networks and can include redundant FortiAP units. Connections to the Internet normally use the wan1 and wan2 interfaces for redundant connections. Connections to internal networks and servers use redundant connections to FortiGate-100D switch ports. FRUP uses the FortiGate-100D switch ports for full mesh HA instead of external redundant switches.

Each device or network has a default active connection to one of the FortiGate units and a default backup connection to the other. Ideally, the default active and backup connections should balance traffic between the FortiGate units in the cluster so that both FortiGate units are processing the same amount of traffic.

FRUP uses virtual IPs and virtual MACs so that when a failover occurs, network devices do not have to learn new IP or MAC addresses. FRUP also synchronizes the configuration between the units in the cluster.

Use the following CLI command on both FortiGate-100D units to configure FRUP.

```
config system ha
    set hbdev "ha1" 50 "ha2" 100
    set override disable
    set priority 128
    set frup enable
    config frup-settings
        set active-interface "wan2"
        set active-switch-port 14
        set backup-interface "wan1"
    end
end
```

Both units must have the same heartbeat device configuration and have FRUP enabled to form a FRUP cluster. Active interface and switch ports must be complementary according to your configuration (see the following example).

## FRUP configuration example

This example includes the following:

- Two FortiGate-100D units (FGT-A and FGT-B)
- HA1 and HA2 for redundant HA heartbeat connectivity between FGT-1 and FGT-2
- Dual gateways (router1 and router2):
  - FGT-A has an active connection from WAN1 to router-1 and a backup connection from WAN2 to router-2
  - FGT-B has an active connection from WAN2 to router-2 and a backup connection from WAN1 to router-1
- Dual connections to the internal network and an internal server:
  - FGT-A has an active connection to an internal server using switch port 16 and a backup connection to the internal network using switch port 14
  - FGT-B has a backup connection to an internal server using switch port 16 and an active connection to the internal network using switch port 14
- FortiGate interfaces use virtual IP addresses and pseudo-MAC physical addresses, all devices continue to send to the same IP/Mac and don't need to re-learn after a failover
- Both FortiGate units will handle and process traffic
- Backup links are normally administratively down
- Sessions and the FortiGate configuration are synchronized between the cluster units

**Figure 223:**Example FRUP configuration

### Configuring FGT-A

Change the host name to FGT-A. Set up FGT-A with dual redundant internet links using WAN1 and WAN2. Set WAN1 and WAN2 interfaces to use static addressing and set both static routes to same priority and distance.

From CLI enter the following command:

```
config system ha
  set hbdev "ha1" 50 "ha2" 100
  set override disable
  set priority 255
  set frup enable
  config frup-settings
    set active-interface "wan1"
    set active-switch-port 16
    set backup-interface "wan2"
  end
end
```

## Configuring FGT-B

Use the same firmware version as FGT-A and set the FortiGate unit to factory defaults. Change the host name to FGT-B.

From CLI enter the following command:

```
config system ha
  set hbdev "ha1" 50 "ha2" 100
  set override disable
  set priority 128
  set frup enable
  config frup-settings
    set active-interface "wan2"
    set active-switch-port 14
    set backup-interface "wan1"
  end
end
```

## Connecting, testing and operating the FRUP cluster

Connect to the FortiGate-100D units to the network as shown in the diagram and power them on. The FortiGate-100D units should find each other and form a cluster.

Traffic from the server (IP: 192.168.1.200) connected to port16 should pass through FGT-A (since port16 is the active-switch-port in FGT-A) and to the Internet using WAN1 (since WAN1 is the active-interface in FGT-A).

Run a sniffer on both FortiGate units using the following command:

```
diagnose sniffer packet any 'icmp' 4
interfaces=[any]
filters=[icmp]
```

Then run a ping to 4.2.2.2 from the server. The sniffer should show results similar to the following:

```

FGT-A # diagnose sniffer packet any 'icmp' 4
interfaces=[any]
filters=[icmp]
0.231160 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
0.231202 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
0.231209 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
1.198520 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
1.198555 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
1.222569 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
1.222589 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
1.222595 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
2.199916 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
2.199952 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
2.232998 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
2.233017 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
2.233023 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
3.201347 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
3.201385 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
3.235406 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
3.235425 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
3.235430 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply

18 packets received by filter
0 packets dropped by kernel

FGT-A #

```

Traffic initiating from a host on the internal network (for example, IP: 192.168.1.114) connected to port14 should flow through FGT-B (since port14 is the active-switch-port in FGT-B) to the Internet using WAN2 (since WAN2 is FGT-B's active interface).

Run the same sniffer on both FortiGate units and then run a ping to 74.125.226.1 from the internal network. The sniffer should show results similar to the following:

```

FGT-B $ diagnose sniffer packet any 'icmp' 4
interfaces=[any]
filters=[icmp]
1.887458 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
1.887488 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
1.887492 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
1.898137 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
1.898153 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
1.898159 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
2.885644 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
2.885682 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
2.885687 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
2.896175 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
2.896194 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
2.896201 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
3.884046 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
3.884091 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
3.884096 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
3.894192 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
3.894213 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
3.894220 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply

18 packets received by filter
0 packets dropped by kernel

```

Shutdown FGT-A.

Traffic from the internal network should be handled by FGT-B using WAN1 and WAN2 interfaces:

```
FGT-B # diagnose sniffer packet any 'icmp' 4
interfaces=[any]
filters=[icmp]
0.954086 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
0.954226 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
0.968696 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
0.968780 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
0.968796 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
1.166934 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
1.166960 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
1.166966 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
1.177525 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
1.177541 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
1.177547 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
1.955117 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
1.955259 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
1.987992 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
1.988084 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
1.988101 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
2.165320 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
2.165346 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
2.165352 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
2.175081 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
2.175098 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
2.175105 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
2.956439 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
2.956583 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
2.973142 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
2.973237 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
2.973255 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
3.163683 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
3.163709 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
3.163714 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
3.174329 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
3.174362 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
3.174369 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
3.957570 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
3.957711 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
3.979899 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
3.979990 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
3.980012 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply

38 packets received by filter

FGT-B #
```

To re-establish the cluster after a failover you need to restart both FortiGate-100D units. Just re-starting FGT-A may not bring the cluster back online.

# Chapter 10 Install and System Administration for FortiOS 5.0

This guide contains the following sections:

[Differences between Models and Firmware](#) highlights key differences that exist between FortiGate models and firmware versions.

[Using the web-based manager](#) provides an overview of the web-based manager interface for FortiOS. If you are new to the FortiOS web-based manager, this chapter provides a high level overview of how to use this method of administration.

[Using the CLI](#) provides an overview of the command line interface (CLI) for FortiOS. If you are new to the FortiOS CLI, this chapter provides a high level overview of how to use this method of administration.

[Basic Administration](#) describes the simple setup requirements an administrator should do to get the FortiGate unit on the network and enabling the flow of traffic.

[Best practices](#) discusses methods to make the various components of FortiOS more efficient and offers suggestions on ways to configure the FortiGate unit.

[FortiGuard](#) discusses the FortiGuard network services and configuration examples.

[FortiCloud](#) discusses the FortiCloud hosted security management and log retention service.

[Interfaces](#) describes the FortiGate interface options and configuration choices.

[Central management](#) describes how to configure the FortiGate unit to use FortiManager as a method of maintaining the device and other features that FortiManager has to facilitate the administration of multiple devices.

[Monitoring](#) describes various methods of collecting log data and tracking traffic flows and trends.

[VLANs](#) discusses the implementation of virtual local area networks (VLANs) in FortiOS and how to configure and use them.

[PPTP and L2TP](#) describes these virtual private network (VPN) types and how to configure them.

[Session helpers](#) describes what session helpers are and how to view and configure them.

[Advanced concepts](#) describes more involved administrative topics to enhance network security and traffic efficiency.

# Differences between Models and Firmware

This section examines some of the key differences that exist between different FortiGate models and different versions of the FortiOS 5.0 firmware. It is important to keep these differences in mind when reading the FortiOS 5.0 Handbook, in order to understand how the documentation relates to your specific FortiGate unit.

## Differences between Models

- There are certain features that are not available on all models. For example, the Switch Controller, which allows a FortiGate unit to manage a FortiSwitch unit, is only available on FortiGate models 100D, 140D, 200D, 240D, 600C, 800C, and 1000C.  
Other features may be available only through the CLI on models, while other models have options in the web-based manager. For example, SSL content inspection is a CLI-only feature on FortiGate models 20C, 30C, and 40C, while models 60C+ have options in the web-based manager.  
For more information about some of the features that vary by model, please see the [Feature/Platform Matrix](#).
- Naming conventions may vary between FortiGate models. For example, on some models the interface used for the local area network is called *lan*, while on other units it is called *internal*.
- Menus may vary by model. For example, on some FortiGate units, the menu option *Router* is not available. Instead, routing is configured by going to *System > Network > Routing*.

## Differences between Firmware Versions

- Many changes are introduced in new patches to the FortiOS 5.0 firmware. For more information about these changes, please see [What's New for FortiOS 5.0](#) and the FortiOS [Release Notes](#).
- In FortiOS 5.0 Patch 3, *Feature Select* was added, which controls which menus are visible in the web-based manager. If a feature you wish to use does not appear in the web-based manager, go to *System > Config > Features* to ensure that the feature has not been turned off.
- Menu names may change between firmware versions. For example, In FortiOS 5.0 Patch 3, the features formerly known *UTM Security Profiles* was renamed *Security Profiles*.
- Menus may move between firmware versions. For example, in FortiOS Patch 5, Endpoint Control moved from being part of the *User* menu to having a menu option of its own, found at *User & Device > Endpoint Protection*.
- Options may also be removed in a firmware patch. For example, in FortiOS Patch 5, the *Client Reputation Monitor* was removed. Client Reputation results can now be found in the *Threat History* widget.

# Using the web-based manager

This section describes the features of the web-based manager administrative interface (sometimes referred to as a graphical user interface, or GUI) of your unit. This section also explains common web-based manager tasks that an administrator does on a regular basis.

The following topics are included in this section:

- [Web-based manager overview](#)
- [Web-based manager menus and pages](#)
- [Entering text strings](#)
- [Dashboard](#)
- [Basic configurations](#)

## Web-based manager overview

The web-based manager is a user-friendly interface for configuring settings and managing the FortiGate unit. Accessing the web-based manager is easy and can be done by using either HTTP or a secure HTTPS connection from any management computer, using a web browser.

The recommended minimum screen resolution for properly displaying the web-based manager is 1280 by 1024. Some web browsers do not correctly display the windows within the web-based manager interface. Verify that you have a supported web browser by reviewing the Knowledge Base articles: [Microsoft Windows web browsers supported by Fortinet products web-based manager \(GUI\) web browsers](#) and [Mac OS browsers for use with Fortinet hardware web-based manager \(GUI\)](#).

The web-based manager also provides the CLI Console widget, which enables you to connect to the command line interface (CLI) without exiting out of the web-based manager.

## Web-based manager menus and pages

The web-based manager provides access to configuration options for most of the FortiOS features from the main menus. The web-based manager contains the following main menus:

<b>System</b>	Configure system settings, such as network interfaces, virtual domains, DHCP and DNS services, administrators, certificates, High Availability (HA), system time, set system options and set display options on the web-based manager.
<b>Router</b>	Configure static, dynamic and multicast routing and view the router monitor.
<b>Policy</b>	Configure firewall policies, protocol options and Central NAT Table.
<b>Firewall Objects</b>	Configure supporting content for firewall policies including scheduling, services, traffic shapers, addresses, virtual IP and load balancing.
<b>Security Profiles</b>	Configure antivirus and email filtering, web filtering, intrusion protection, data leak prevention, application control, VOIP, ICAP and Client Reputation.

<b>VPN</b>	Configure IPsec and SSL virtual private networking.
<b>User &amp; Device</b>	Configure user accounts and user authentication including external authentication servers. This menu also includes endpoint security features, such as FortiClient configuration and application detection patterns.
<b>WAN Opt. &amp; Cache</b>	Configure WAN optimization and web caching to improve performance and security of traffic passing between locations on your wide area network (WAN) or from the Internet to your web servers.
<b>WiFi &amp; Switch Controller</b>	Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units.
<b>Log &amp; Report</b>	Configure logging and alert email as well as reports. View log messages and reports.
<b>Current VDOM</b>	Appears only when VDOMs are enabled on the unit to switch between VDOMs.

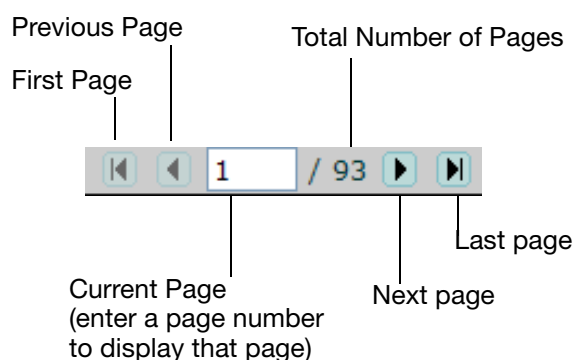

## Using information tables

Many of the web-based manager pages contain tables of information that you can filter to display specific information. Administrators with read and write access can define the filters.

## Using page navigation

Some pages contain information and lists that span multiple pages. At the bottom of the page is the page navigation controls that enables you to move between pages.

**Figure 224:**Page controls

## Adding filters to web-based manager lists

Filters are used to locate a specific set of information or content within multiple pages. These are especially useful in locating specific log entries. The specific filtering options vary, depending on the type of information in the log.

To create a filter, select *Filter Settings* or the filter icon in a column heading. When a filter is applied to a column, the filter icon becomes green. Filter settings are stored in the unit's configuration and will be maintained the next time that you access any list for which you have added filters.

Filtering variables can include: a numeric range (such as 25-50), an IP address or part of an address or any text string combination, including special characters.

Note that the filtering ignores characters following a “<” unless the followed by a space. For example, the filtering ignores `<string` but not `< string`. Filtering also ignores matched opening and closing (`<` and `>`) characters and any characters between them. For example, filtering will ignore `<string>`.

For columns that contain only specific content, such as log message severity, a list of terms is provided from which options can be selected.

## Using column settings

Column settings are used to select the types of information which are displayed on a certain page. Some pages have a large amounts of information is available and not all content can be displayed on a single screen. Also, some pages may contain content that is not of use to you. Using column settings, you can display only that content which is important to your requirements.

To configure column settings, right-click the header of a column and select *Column Settings*. Any changes that you make to the column settings of a list are stored in the unit’s configuration and will display the next time that you access the list.

To return a page’s columns to their default state, select *Reset All Columns*, located at the bottom of the *Column Settings* menu.

## Entering text strings

The configuration of a FortiGate unit is stored in the FortiOS configuration database. To change the configuration, you can use the web-based manager or CLI to add, delete, or change configuration settings. These changes are stored in the database as you make them.

Individual settings in the configuration database can be text strings, numeric values, selections from a list of allowed options, or on/off (enable/disable) settings.

### Entering text strings (names)

Text strings are used to name entities in the configuration. For example, the name of a firewall address, administrative user, and so on. You can enter any character in a FortiGate configuration text string except, to prevent Cross-Site Scripting (XSS) vulnerabilities, the following characters:

“ (double quote), & (ampersand), ' (single quote), < (less than) and > (greater than)

Most web-based manager text string fields make it easy to add an acceptable number of characters and prevent you from adding the XSS vulnerability characters.

There is a different character limitation for VDOM names and hostnames. For both, the only legal characters are numbers (0-9), letters (a-z, A-Z), and special characters - and \_.

---

From the CLI, you can also use the `tree` command to view the number of characters that are allowed in a name field. For example, firewall address names can contain up to 64 characters. When you add a firewall address to the web-based manager, you are limited to entering 64

characters in the firewall address name field. From the CLI you can enter the following `tree` command to confirm that the firewall address `name` field allows 64 characters.

```
config firewall address
tree
-- [address] --*name (64)
    | - subnet
    | - type
    | - start-ip
    | - end-ip
    | - fqdn (256)
    | - cache-ttl (0,86400)
    | - wildcard
    | - comment (64 xss)
    | - associated-interface (16)
+- color (0,32)
```

The `tree` command output also shows the number of characters allowed for other firewall address name settings. For example, the fully-qualified domain name (`fqdn`) field can contain up to 256 characters.

## Entering numeric values

Numeric values set various sizes, rates, numeric addresses, and other numeric values. For example, a static routing priority of 10, a port number of 8080, or an IP address of 10.10.10.1. Numeric values can be entered as a series of digits without spaces or commas (for example, 10 or 64400), in dotted decimal format (for example the IP address 10.10.10.1) or, as in the case of MAC or IPv6 addresses, separated by colons (for example, the MAC address 00:09:0F:B7:37:00). Most numeric values are standard base-10 numbers, but some fields (again, such as MAC addresses) require hexadecimal numbers.

Most web-based manager numeric value fields make it easy to add the acceptable number of digits within the allowed range. CLI help includes information about allowed numeric value ranges. Both the web-based manager and the CLI prevent you from entering invalid numbers.

## Enabling or disabling options

If a configuration option can only be on or off (enabled or disabled), the web-based manager presents a check box or other control that can only be enabled or disabled. From the CLI you can set the option to `enable` or `disable`.

## Dashboard

The various dashboard menus provides a way to access information about network activity and events, as well as configure basic system settings. You can easily add more dashboards and edit existing ones to easily view the content you need.

Each information “chunk” is found within a widget. Widgets provide an easy and quick way to view a variety of information, such as statistical information or network activity. There are a selection of widgets to choose from by selecting the *Widgets* option.

Administrators must have read and write privileges for adding and configuring dashboards and widgets.

## Adding dashboards and widgets

Dashboards that you create are automatically added under the default status and usage dashboards. You can add, remove, or rename a dashboard, regardless of whether it is default. You can also reset the Dashboard menu to its default settings by selecting *Reset Dashboards*.

If VDOMs are enabled, only the dashboards within Global are available for configuration.

### To add a dashboard

1. Go to *System > Dashboard > Status*.
2. Select *Dashboard*, located at the top left of the page.
3. Select *Add Dashboard*.

To add a widget to a dashboard, select *Widget* located at the top left of the dashboard page.

## System Information widget

The *System Information* widget shows status information on the FortiGate unit and provides the access point to update the firmware and backup the configurations.

<b>Host Name</b>	<p>The name of the FortiGate unit. For details on changing the name, see <a href="#">Changing the FortiGate unit's host name</a>.</p> <p>If the FortiGate unit is in HA mode, this information is not displayed.</p>
<b>Serial Number</b>	<p>The serial number of the FortiGate unit. The serial number is specific to that FortiGate unit and does not change with firmware upgrades.</p>
<b>Operation Mode</b>	<p>The current operating mode of the FortiGate unit. A FortiGate unit can operate in NAT mode or Transparent mode. Select <i>Change</i> to switch between NAT and transparent mode. For more information, see <a href="#">Changing the operation mode</a>.</p> <p>If virtual domains are enabled, this field shows the operating mode of the current virtual domain. The Global System Status dashboard does not include this information.</p>
<b>HA Status</b>	<p>The status of High Availability (HA) within the cluster. Standalone indicates the FortiGate unit is not operating in HA mode. Active-Passive or Active-Active indicate the FortiGate unit is operating in HA mode. Select <i>Configure</i>, to change the HA configuration.</p>
<b>Cluster Name</b>	<p>The name of the HA cluster for this FortiGate unit. The FortiGate unit must be operating in HA mode to display this field.</p>
<b>Cluster Members</b>	<p>The FortiGate units in the HA cluster. Information displayed about each member includes host name, serial number, and whether the FortiGate unit is a primary (master) or subordinate (slave) FortiGate unit in the cluster.</p> <p>The FortiGate unit must be operating in HA mode with virtual domains disabled to display this information.</p>
<b>Virtual Cluster 1</b> <b>Virtual Cluster 2</b>	<p>The role of each FortiGate unit in virtual cluster 1 and virtual cluster 2.</p> <p>The FortiGate unit must be operating in HA mode with virtual domains enabled to display this information.</p>

<b>System Time</b>	The current date and time. Select <i>Change</i> , to configure the system time. For more information, see <a href="#">Configuring system time</a> .
<b>Firmware Version</b>	The version of the current firmware installed on the FortiGate unit. Select <i>Update</i> to upload a different firmware version. For more information, see <a href="#">Changing the firmware</a> .
<b>System Configuration</b>	<p>The time period of when the configuration file was backed up. Select <i>Backup</i> to back up the current configuration. For more information, see <a href="#">Backing up the configuration</a>.</p> <p>To restore a configuration file, select <i>Restore</i>. For more information, see <a href="#">Restoring your firmware configuration</a>.</p>
<b>Current Administrator</b>	<p>The number of administrators currently logged into the FortiGate unit.</p> <p>Select <i>Details</i> to view more information about each administrator that is currently logged in</p> <p>If you want to changed the current administrator's password, see <a href="#">Changing the currently logged in administrator's password</a>.</p>
<b>Uptime</b>	The time in days, hours, and minutes since the FortiGate unit was started or rebooted.
<b>Virtual Domain</b>	<p>Status of virtual domains on your FortiGate unit. Select <i>Enable</i> or <i>Disable</i> to change the status of virtual domains feature.</p> <p>If you enable or disable virtual domains, your session will be terminated and you will need to log in again.</p>
<b>Explicit Proxy Load Balance</b>	The status of each feature. Select <i>Enable</i> or <i>Disable</i> to change the status of the feature. When enabled, the menu option appears.

## Changing the FortiGate unit's host name

The host name appears in the *Host Name* row, in the *System Information* widget. The host name also appears at the CLI prompt when you are logged in to the CLI and as the SNMP system name.

To change the host name on the FortiGate unit, in the *System Information* widget, select *Change* in the *Host Name* row. The only administrators that can change a FortiGate unit's host name are administrators whose admin profiles permit system configuration write access. If the FortiGate unit is part of an HA cluster, you should use a unique host name to distinguish the FortiGate unit from others in the cluster.

## Changing the operation mode

FortiGate units and individual VDOMs can operate in NAT or Transparent mode. From the *System Information* dashboard widget, you can change the operating mode for your FortiGate unit or for a VDOM and perform sufficient network configuration to ensure that you can connect to the web-based manager in the new mode.

### NAT mode

In NAT mode, the FortiGate unit is visible to the network that it is connected to and all of its interfaces are on different subnets. Each interface that is connected to a network must be configured with an IP address that is valid for that subnet.

You would typically use NAT mode when the FortiGate unit is deployed as a gateway between private and public networks (or between any networks). In its default NAT mode configuration,

the FortiGate unit functions as a router, routing traffic between its interfaces. Security policies control communications through the FortiGate unit to both the Internet and between internal networks. In NAT mode, the FortiGate unit performs network address translation before IP packets are sent to the destination network.

For example, a company has a FortiGate unit as their interface to the Internet. The FortiGate unit also acts as a router to multiple subnets within the company. In this situation, the FortiGate unit is set to NAT mode and has a designated port for the Internet, wan1, with an address of 172.20.120.129, which is the public IP address. The internal network segments are behind the FortiGate unit and invisible to the public access, for example port 2 has an address of 10.10.10.1. The FortiGate unit translates IP addresses passing through it to route the traffic to the correct subnet or to the Internet.

### **Transparent Mode**

In transparent mode, the FortiGate unit is invisible to the network. All of its interfaces are on the same subnet and share the same IP address. To connect the FortiGate unit to your network, all you have to do is configure a management IP address and a default route.

You would typically use the FortiGate unit in transparent mode on a private network behind an existing firewall or behind a router. In transparent mode, the FortiGate unit also functions as a firewall. Security policies control communications through the FortiGate unit to the Internet and internal network. No traffic can pass through the FortiGate unit until you add security policies.

For example, the company has a router or other firewall in place. The network is simple enough that all users are on the same internal network. They need the FortiGate unit to perform application control, antivirus, intrusion protection, and similar traffic scanning. In this situation, the FortiGate unit is set to transparent mode. The traffic passing through the FortiGate unit does not change the addressing from the router to the internal network. Security policies and security profiles define the type of scanning the FortiGate unit performs on traffic entering the network.

#### **To switch from NAT to transparent mode**

1. From the *System Information* dashboard widget select *Change* beside *Operation Mode*.
2. From the *Operation Mode* list, select *Transparent*.
3. Enter the *Management IP* address and Netmask. This is the IP address to connect to when configuring and maintaining the device.
4. Enter the *Default Gateway*.
5. Select *OK*.

#### **To change the transparent mode management IP address**

1. From the *System Information* dashboard widget select *Change* beside *Operation Mode*.
2. Enter a new IP address and netmask in the *Management IP/Network* field as required and select *OK*.

Your web browser is disconnected from the web-based manager. To reconnect to the web-based manager browse to the new management IP address.

#### **To switch from transparent to NAT mode**

1. From the *System Information* dashboard widget select *Change* beside *Operation Mode*.
2. From the *Operation Mode* list, select *NAT*.
3. Enter valid IP address and netmask for the network from which you want to manage the FortiGate unit.
4. Select the interface to which the Interface IP/Netmask settings apply
5. Enter the IP address default gateway required to reach other networks from the FortiGate unit.

6. After the FortiGate unit switches to NAT mode, you may need to go *Router > Static Route* and edit this default route.  
For low-end FortiGate units, go to *System > Network > Routing*.
7. Select OK.

## Configuring system time

The FortiGate unit's system time can be changed using the *System Information* widget by selecting *Change* in the *System Time* row.

<b>System Time</b>	The current system date and time on the FortiGate unit.
<b>Refresh</b>	Update the display of the FortiGate unit's current system date and time.
<b>Time Zone</b>	Select the current system time zone for the FortiGate unit.
<b>Set Time</b>	Select to set the system date and time to the values.
<b>Synchronize with NTP Server</b>	Select to use a Network Time Protocol (NTP) server to automatically set the system date and time. You must specify the server and synchronization interval.  FortiGate units use NTP Version 4. For more information about NTP see <a href="http://www.ntp.org">http://www.ntp.org</a> .
<b>Server</b>	Enter the IP address or domain name of an NTP server. To find an NTP server that you can use, see <a href="http://www.ntp.org">http://www.ntp.org</a> .
<b>Sync Interval</b>	Specify how often the FortiGate unit should synchronize its time with the NTP server.
<b>Enable NTP Server</b>	Select to make the FortiGate unit an NTP server that client computers can ping for time synchronization. When selected, the Listen on Interfaces option appears. Add the interfaces the FortiGate unit will listen for time requests.

Daylight savings time is enabled by default. You can disable daylight savings time using the CLI commands:

```
config system global
    set dst disable
end
```

## Changing the firmware

To avoid losing configuration settings you should always back up your configuration before changing the firmware image.

Also, when updating firmware, you should first refer to [Supported Upgrade Paths for FortiOS Firmware](#) to help ensure a successful upgrade.

Administrators whose admin profiles permit maintenance read and write access can change the FortiGate unit's firmware. Firmware images can be installed from a number of sources including a local hard disk, a local USB disk, or the FortiGuard Network.

To change the firmware, go to *System > Dashboard > Status > System Information* widget and select the *Update* link on the *Firmware Version* row.

<b>Upgrade From</b>	Select the firmware source from the drop down list of available sources.
<b>Firmware Version</b>	<p>This appears only when selecting <i>FortiGuard Network</i> is selected from the <i>Upgrade From</i> drop-down list. Select a firmware version from the drop-down list.</p> <p>If downgrading the firmware on the FortiGate unit, select the check box beside Allow Firmware Downgrade.</p>
<b>Upgrade File</b>	<p>Browse to the location of the firmware image on your local hard disk.</p> <p>This field is available for local hard disk and USB only.</p>
<b>Allow Firmware Downgrade</b>	<p>Select to confirm the installation of an older firmware image (downgrade).</p> <p>This appears only when selecting <i>FortiGuard Network</i> is selected from the <i>Upgrade From</i> drop-down list.</p>
<b>Upgrade Partition</b>	<p>The number of the partition being updated.</p> <p>This field is available only if your FortiGate unit has more than one firmware partition.</p>
<b>Boot the New Firmware</b>	<p>By default, this is enabled. Select to disable the FortiGate unit's reboot process when installing a firmware image to a partition.</p> <p>This option enables you to install a firmware image to a partition without the FortiGate unit rebooting itself and making the firmware image the default firmware that is currently running.</p>

You need to register your FortiGate unit with Customer Support to access firmware updates for your model. For more information, go to <http://support.fortinet.com> or contact Customer Support.

## Backing up the configuration

Administrators can back up the FortiGate unit's configuration file from the *System Information* widget. Select *Backup* in the *System Configuration* row, to back up the firmware configuration file to a local computer, USB disk or to a FortiManager unit.

You should always back up your configuration whenever you make any modifications to the device configuration or performing any firmware updates or changes.

<b>Local PC</b>	Select to back up the configuration file to a local management computer.
<b>FortiManager</b>	<p>Select to back up the configuration file to a FortiManager unit. The Central Management settings must be enabled and a FortiManager unit connected with the FortiGate unit so that the FortiGate unit can send the configuration file to the FortiManager unit.</p> <p>To enable central management, go to <i>System &gt; Admin &gt; Settings</i>.</p>

<b>USB Disk</b>	Select to back up the configuration file to a USB key that is connected to the FortiGate unit.
<b>Full Config</b>	Select to backup the full VDOM configuration. This appears only when the FortiGate unit has VDOM configuration enabled.
<b>VDOM Config</b>	Select to backup the only the VDOM configuration file. This option backs up only the configuration file within that VDOM. Select the VDOM from the drop-down list, and select <i>Backup</i> .
<b>Encrypt configuration file</b>	Select to enable a password to the configuration file for added security.
<b>Password</b>	Enter the password that will be used to restore the configuration file.
<b>Confirm</b>	Re-enter the password.

## Formatting USB

The FortiGate unit enables you to back up the configuration of the device to a USB flash drive. The USB flash drive must be formatted as a FAT16 disk.

To format the USB flash drive, either use the CLI command `exe usb-disk format.` or within Windows at a command prompt, enter the command

```
format <drive_letter>: /FS:FAT /V:<drive_label>
```

where *<drive\_letter>* is the letter of the connected USB flash drive and *<drive\_label>* is the name to give the USB drive.

## Remote FortiManager backup and restore options

After successfully connecting to the FortiManager unit from your FortiGate unit, you can back up and restore your configuration to and from the FortiManager unit.

A list of revisions is displayed when restoring the configuration from a remote location. The list allows you to choose the configuration to restore. To use the FortiManager unit as a method of backup and restore of configuration files, you must first configure a connection between the two devices. For more information, see [Central management](#).

## Remote FortiGuard backup and restore options

Your FortiGate unit can be remotely managed by a central management server that is available when you register for the FortiGuard Analysis and Management Service. FortiGuard Analysis and Management Service is a subscription-based service and is purchased by contacting support.

After registering, you can back up or restore your configuration. FortiGuard Analysis and Management Service is useful when administering multiple FortiGate units without having a FortiManager unit. Using this service, you can also upgrade the firmware. Upgrading the firmware is available in the *Firmware Upgrade* section of the backup and restore menu.

When restoring the configuration from a remote location, a list of revisions is displayed so that you can choose the configuration file to restore.

The FortiGuard-FortiManager protocol is used when connecting to the FortiGuard Analysis and Management Service. This protocol runs over SSL using IPv4/TCP port 541 and includes the following functions:

- detects FortiGate unit dead or alive status
- detects management service dead or alive status
- notifies the FortiGate units about configuration changes, AV/IPS database update and firewall changes.

## Restoring your firmware configuration

Administrators can restore a configuration file that was backed up using the *System Information* widget. If the configuration file was encrypted, you will need the password to restore the configuration file.

<b>Local PC</b>	Select to back up the configuration file to a local management computer.
<b>FortiManager</b>	Select to back up the configuration file to a FortiManager unit. The Central Management settings must be enabled and a FortiManager unit connected with the FortiGate unit so that the FortiGate unit can send the configuration file to the FortiManager unit.  To enable central management, go to <i>System &gt; Admin &gt; Settings</i> .
<b>USB Disk</b>	Select to back up the configuration file to a USB key that is connected to the FortiGate unit.
<b>Filename</b>	Select Browse to locate the configuration file.
<b>Password</b>	If a password was set when saving the configuration file, enter the password.

## Viewing online administrators

The *System Information* widget enables you to view information about the administrators logged into the FortiGate unit. To view logged in administrators, in the *System Information* widget, select *Details*.

## Changing the currently logged in administrator's password

Use the *System Information* widget, to change your password. To do this, select the *Change Password* option in the *Current Administrator* row.

## License Information widget

The *License Information* widget displays the status of your technical support contract and FortiGuard subscriptions. The FortiGate unit updates the license information status indicators automatically when attempting to connect to the FortiGuard Distribution Network (FDN). FortiGuard Subscriptions status indicators are green if the FDN was reachable and the license was valid during the last connection attempt, grey if the FortiGate unit cannot connect to the FDN, and orange if the FDN is reachable but the license has expired.

When a new FortiGate unit is powered on, it automatically searches for FortiGuard services. If the FortiGate unit is configured for central management, it will look for FortiGuard services on the configured FortiManager system. The FortiGate unit sends its serial number to the FortiGuard service provider, which then determines whether the FortiGate unit is registered and has valid contracts for FortiGuard subscriptions and FortiCare support services. If the FortiGate unit is registered and has a valid contract, the License Information is updated.

If the FortiGate unit is not registered, any administrator with the `super_admin` profile sees a reminder message that provides access to a registration form.

When a contract is due to expire within 30 days, any administrator with the `super_admin` profile sees a notification message that provides access to an Add Contract form. Simply enter the new contract number and select *Add*. Fortinet Support also sends contract expiry reminders.

You can optionally disable notification for registration or contract inquiry using the `config system global` command in the CLI. Selecting any of the *Configure* options will take you to the Maintenance page.

<b>Support Contract</b>	Displays details about your current Fortinet Support contract. <ul style="list-style-type: none"> <li>• If <i>Not Registered</i> appears, select <i>Register</i> to register the FortiGate unit.</li> <li>• If <i>Expired</i> appears, select <i>Renew</i> for information on renewing your technical support contract. Contact your local reseller.</li> <li>• If <i>Registered</i> appears, the name of the support that registered this FortiGate unit is also displayed. The various types of contracts that you currently have and the expiry date for each type.</li> <li>• You can select <i>Login Now</i> to log into the Fortinet Support account that registered this FortiGate unit.</li> </ul>
<b>FortiGuard Services</b>	Displays your current licenses for services from FortiGuard. Select <i>Renew</i> to update any of the licenses.
<b>FortiCloud</b>	Displays details about your current FortiCloud subscription. If the green <i>Activate</i> button appears, select it to either create a new account or add the FortiGate unit to an existing account.  If you have already activated FortiCloud, the name of the <i>Account</i> will be listed. Select <i>Launch Portal</i> to view your FortiCloud account in a web browser.  Information on the current <i>Type</i> and <i>Storage</i> is also listed. You can select <i>Upgrade</i> to change the type of your FortiCloud account.
<b>FortiClient Software</b>	Displays FortiClient license details and the number of <i>Register</i> and <i>Allowed</i> FortiClient users. You can select <i>Details</i> for more information about the current FortiClient users.
<b>FortiToken Mobile</b>	Displays the number of <i>Assigned</i> and <i>Allowed</i> FortiTokens.
<b>SMS</b>	Displays the number of <i>Sent</i> and <i>Allowed</i> SMS messages. You can select <i>Add Messages</i> to configure a new SMS message.
<b>Virtual Domain</b>	Displays the maximum number of virtual domains the FortiGate unit supports with the current license.  For high-end models, you can select the <i>Purchase More</i> link to purchase a license key through Fortinet technical support to increase the maximum number of VDOMs.

## FortiGate unit Operation widget

The *Unit Operation* widget is an illustrated version of the FortiGate unit's front panel that shows the status of the FortiGate unit's network interfaces. Interfaces appear green when connected. Hover the mouse pointer over an interface to view further details.

Icons around the front panel indicate when the FortiGate unit is connected to a FortiAnalyzer or FortiManager device, or FortiClient installations. Select the icon in the widget to jump to the configuration page for each device. When connected to one of these devices, a green check mark icon appears next to the icon. If the device communication is configured but the device is unreachable, a red X appears.

## System Resources widget

The *System Resources* widget displays basic FortiGate unit resource usage. This widget displays the information for CPU and memory in either real-time or historical data. For FortiGate units with multiple CPUs, you can view the CPU usage as an average of all CPUs or each one individually.

This widget also is where you reboot or shutdown the FortiGate unit.

The options to reboot or shutdown the FortiGate unit are not available for an admin using the *prof\_admin* profile.

Use the *Refresh* icon when you want to view current system resource information, regardless of whether you are viewing real-time or historical type format.

To change the resource view from real-time to historical, or change the CPU view (for multiple CPU FortiGate units), select the *Edit* icon (visible when you hover the mouse over the widget).

When viewing CPU and memory usage in the web-based manager, only the information for core processes displays. CPU for management processes, is excluded. For example, HTTPS connections to the web-based manager.

## Alert Message Console widget

The *Alert Messages Console* widget helps you monitor system events on your FortiGate unit such as firmware changes, network security events, or virus detection events. Each message shows the date and time that the event occurred.

You can configure the alert message console settings to control what types of messages are displayed on the console.

### To configure the Alert Message Console

1. Locate the *Alert Message Console* widget within the Dashboard menu.
2. Select the *Edit* icon in the *Alert Message Console* title bar.
3. Select the types of alerts that you do not want to be displayed in the widget.
4. Select *OK*.

## CLI Console widget

The *CLI Console* widget enables you to access the CLI without exiting from the web-based manager.

The two controls located on the CLI Console widget title bar are *Customize*, and *Detach*.

- *Detach* moves the CLI Console widget into a pop-up window that you can resize and reposition. Select *Attach*. to move the widget back to the dashboard's page.
- *Customize* enables you to change the appearance of the console by selecting fonts and colors for the text and background.

## Session History widget

The *Session History* widget displays the total session activity on the device. Activity displays on a per second basis. Select the *Edit* icon in the title bar (which appears when you hover the mouse over the widget) to change the time period for the widget.

## Top Sessions widget

The *Top Sessions* widget polls the FortiGate unit for session information for IPv4 or IPv6 addresses, or both. Rebooting the FortiGate unit will reset the Top Session statistics to zero.

When you select *Details* to view the current sessions list, a list of all sessions currently processed by the FortiGate unit.

Detailed information is available in *System > Monitor > Sessions*. Use the following table to modify the default settings of the Top Sessions widget.

## USB Modem widget

The *USB modem* widget enables you to monitor the status of your USB modem, and configure it as needed.

## Advanced Threat Protection Statistics widget

The *Advanced Threat Protection Statistics* widget displays a count of detected malware and files scanned for these types of intrusions. It also displays statics on the number of files sent to FortiSandbox and the results from sandboxing.

## Features widget

The *Features* widget displays a number of *Basic Features* and *Security Features* and whether or not each feature is currently enabled or disabled. Options for features that are disabled will not appear in the web-based manager.

For *Security Features*, several *Preset* options are available, which can be selected from the dropdown menu in the widget:

- *UTM* enabled all security features and should be chosen for networks that require full protection from FortiOS. *UTM* is the default setting.
- *WF* enables web filtering features.
- *ATP* enables protection against viruses and other external threats.
- *NGFW* enables application control and protection from external attacks.
- *NGFW + ATP* enables features that protect against external threats and attacks.

## RAID monitor widget

The *RAID Monitor* widget displays the current state of the RAID array and each RAID disk. This widget does not display unless the FortiGate unit has more than one disk installed and is not available for FortiOS Carrier.

<b>Array status icon</b>	<p>Displays the status of the RAID array.</p> <ul style="list-style-type: none"><li>• Green with a check mark shows a healthy RAID array.</li><li>• Yellow triangle shows the array is in a degraded state but it is still functioning. A degraded array is slower than a healthy array. Rebuild the array to fix the degraded state.</li><li>• A wrench shows the array is being rebuilt.</li></ul> <p>Positioning the mouse over the array status icon displays a text message of the status of the array.</p>
<b>Disk status icon</b>	<p>There is one icon for each disk in the array.</p> <ul style="list-style-type: none"><li>• Green with a check mark shows a healthy disk.</li><li>• Red with an X shows the disk has failed and needs attention.</li></ul> <p>Positioning the mouse over the disk status icon displays the status of the disk, and the storage capacity of the disk.</p>
<b>RAID Level</b>	<p>The RAID level of this RAID array. The RAID level is set as part of configuring the RAID array.</p>
<b>Status bar</b>	<p>The bar shows the percentage of the RAID array that is currently in use.</p>
<b>Used/Free/Total</b>	<p>Displays the amount of RAID array storage that is being used, the amount of storage that is free, and the total storage in the RAID array. The values are in gigabytes.</p>

## RAID disk configuration

The RAID disk is configured from the Disk Configuration page.

<b>RAID level</b>	<p>Select the level of RAID. Options include:</p> <ul style="list-style-type: none"><li>• <b>RAID-0</b> — (striping) better performance, no redundancy</li><li>• <b>RAID-1</b> — (mirroring) half the storage capacity, with redundancy</li><li>• <b>RAID-5</b> — striping with parity checking, and redundancy</li></ul> <p>Available RAID level options depend on the available number of hard disks. Two or more disks are required for RAID 0 or RAID 1. Three or more disks are required for RAID 5.</p> <p>Changing the RAID level will erase any stored log information on the array, and reboot the FortiGate unit. The FortiGate unit will remain offline while it reconfigures the RAID array. When it reboots, the array will need to synchronize before being fully operational.</p>
-------------------	--

<b>Status</b>	<p>The status, or health, of RAID array. This status can be one of:</p> <ul style="list-style-type: none"> <li>• <b>OK</b> — standard status, everything is normal</li> <li>• <b>OK (Background-Synchronizing) (%)</b> — synchronizing the disks after changing RAID level, Synchronizing progress bar shows percent complete</li> <li>• <b>Degraded</b> — One or more of the disks in the array has failed, been removed, or is not working properly. A warning is displayed about the lack of redundancy in this state. Also, a degraded array is slower than a healthy array. Select <i>Rebuild RAID</i> to fix the array.</li> <li>• <b>Degraded (Background-Rebuilding) (%)</b> — The same as degraded, but the RAID array is being rebuilt in the background. The array continues to be in a fragile state until the rebuilding is completed.</li> </ul>
<b>Size</b>	<p>The size of the RAID array in gigabytes (GB). The size of the array depends on the RAID level selected, and the number of disks in the array.</p>
<b>Rebuild RAID</b>	<p>Select to rebuild the array after a new disk has been added to the array, or after a disk has been swapped in for a failed disk.</p> <p>If you try to rebuild a RAID array with too few disks you will get a rebuild error. After inserting a functioning disk, the rebuild will start.</p> <p>This button is only available when the RAID array is in a degraded state and has enough disks to be rebuilt.</p> <p>You cannot restart a rebuild once a rebuild is already in progress.</p> <p><b>Note:</b> If a disk has failed, the number of working disks may not be enough for the RAID level to function. In this case, replace the failed disk with a working disk to rebuild the RAID array.</p>
<b>Disk#</b>	<p>The disk's position in the array. This corresponds to the physical slot of the disk.</p> <p>If a disk is removed from the FortiGate unit, the disk is marked as not a member of the array and its position is retained until a new disk is inserted in that drive bay.</p>
<b>Status</b>	<p>The status of this disk. Options include OK, and unavailable.</p> <p>A disk is unavailable if it is removed or has failed.</p>

## Basic configurations

Before going ahead and configuring security policies, users, and security profiles, you should perform some basic configurations to set up your FortiGate unit.

### Changing your administrator password

By default, you can log in to the web-based manager by using the admin administrator account and no password. It is highly recommended that you add a password to the admin administrator account. For improved security, you should regularly change the admin administrator account password and the passwords for any other administrator accounts that you add.

To change an administrator's password, go to *System > Admin > Administrators*, edit the administrator account, and then change the password.

For details on selecting a password, and password best practices, see [“Passwords” on page 1429](#).

For information about resetting a lost administrator's password, see [docs.fortinet.com/sysadmin.html](https://docs.fortinet.com/sysadmin.html).

## Changing the web-based manager language

The default language of the web-based manager is English. To change the language, go to *System > Admin > Settings*. In the *Display Settings* section, select the language you want from the *Language* drop-down list.

For best results, you should select the language that the management computer operating system uses.

## Changing administrative access

Through administrative access, an administrator can connect to the FortiGate unit. Access is available through a number of services, including HTTPS and SSH. The default configuration allows administrative access to one or more of the unit's interfaces as described in the [QuickStart Guide](#).

### To change administrative access

1. Go to *System > Network > Interface*.
2. Select the interface.
3. Select the administrative access type or types for that interface.
4. Select *OK*.

## Changing the web-based manager idle timeout

By default, the web-based manager disconnects administrative sessions if no activity occurs for five minutes. This prevents someone from using the web-based manager if the management PC is left unattended.

### To change the idle timeout

1. Go to *System > Admin > Settings*.
2. In the *Administration Settings* section, enter the time in minutes in the *Idle Timeout* field.
3. Select *Apply*.

## Switching VDOMs

When VDOMs are enabled, a menu appears in the left column called *Current VDOM*. This menu displays a drop-down list that lists the configured VDOMs.

To switch to a VDOM using the *Current VDOM* menu, select the VDOM that you want to switch to from the drop-down list. You are automatically redirected to that VDOM.

VDOMs are enabled on the *System Information* Dashboard Widget.

## Connecting to the CLI from the web-based manager

You can use the CLI to configure all configuration options available from the web-based manager. Some configuration options are available only from the CLI.

To connect to the CLI console, go to *System > Dashboard > Status* and select inside the window of the *CLI Console* widget to automatically connect. For more information on using the CLI, see [“Using the CLI” on page 1405](#).

## Logging out

Select the Logout icon to quit your administrative session. If you only close the browser or leave the web-based manager to surf to another web site, you remain logged in until the idle timeout (default 5 minutes) expires. To change the timeout, see [“Changing the web-based manager idle timeout” on page 1403](#).

# Using the CLI

The command line interface (CLI) is an alternative configuration tool to the web-based manager. While the configuration of the web-based manager uses a point-and-click method, the CLI requires typing commands or uploading batches of commands from a text file, like a configuration script.

This section also explains common CLI tasks that an administrator does on a regular basis and includes the topics:

- [Connecting to the CLI](#)
- [Command syntax](#)
- [Sub-commands](#)
- [Permissions](#)
- [Tips](#)

## Connecting to the CLI

You can access the CLI in two ways:

- **Locally** — Connect your computer directly to the FortiGate unit's console port. Local access is required in some cases:
  - If you are installing your FortiGate unit for the first time and it is not yet configured to connect to your network, unless you reconfigure your computer's network settings for a peer connection, you may only be able to connect to the CLI using a local serial console connection. For more information, see [“Connecting to the CLI” on page 1427](#).
  - Restoring the firmware utilizes a boot interrupt. Network access to the CLI is not available until after the boot process has completed, making local CLI access the only viable option.
- **Through the network** — Connect your computer through any network attached to one of the FortiGate unit's network ports. The network interface must have enabled Telnet or SSH administrative access if you will connect using an SSH/Telnet client, or HTTP/HTTPS administrative access if you will connect using the *CLI Console* widget in the web-based manager.

### Connecting to the CLI using a local console

Local console connections to the CLI are formed by directly connecting your management computer or console to the FortiGate unit, using its DB-9 or RJ-45 console port. To connect to the local console you need:

- a computer with an available serial communications (COM) port
- the RJ-45-to-DB-9 or null modem cable included in your FortiGate package
- terminal emulation software such as HyperTerminal for Microsoft Windows

The following procedure describes connection using Microsoft HyperTerminal software; steps may vary with other terminal emulators.

#### To connect to the CLI using a local serial console connection

1. Using the null modem or RJ-45-to-DB-9 cable, connect the FortiGate unit's console port to the serial communications (COM) port on your management computer.
2. On your management computer, start HyperTerminal.
3. For the *Connection Description*, enter a *Name* for the connection, and select *OK*.
4. On the *Connect using* drop-down list box, select the communications (COM) port on your management computer you are using to connect to the FortiGate unit.
5. Select *OK*.
6. Select the following *Port* settings and select *OK*.

<b>Bits per second</b>	9600
<b>Data bits</b>	8
<b>Parity</b>	None
<b>Stop bits</b>	1
<b>Flow control</b>	None

7. Press Enter or Return on your keyboard to connect to the CLI.
8. Type a valid administrator account name (such as `admin`) and press Enter.
9. Type the password for that administrator account and press Enter. (In its default state, there is no password for the `admin` account.)

The CLI displays the following text:

```
Welcome!
```

```
Type ? to list available commands.
```

You can now enter CLI commands, including configuring access to the CLI through SSH or Telnet. For details, see [“Enabling access to the CLI through the network \(SSH or Telnet\)” on page 1406](#).

### Enabling access to the CLI through the network (SSH or Telnet)

SSH or Telnet access to the CLI is accomplished by connecting your computer to the FortiGate unit using one of its RJ-45 network ports. You can either connect directly, using a peer connection between the two, or through any intermediary network.

If you do not want to use an SSH/Telnet client and you have access to the web-based manager, you can alternatively access the CLI through the network using the *CLI Console* widget in the web-based manager.

---

You must enable SSH and/or Telnet on the network interface associated with that physical network port. If your computer is not connected directly or through a switch, you must also configure the FortiGate unit with a static route to a router that can forward packets from the FortiGate unit to your computer. You can do this using either a local console connection or the web-based manager.

## Requirements

- a computer with an available serial communications (COM) port and RJ-45 port
- terminal emulation software such as HyperTerminal for Microsoft Windows
- the RJ-45-to-DB-9 or null modem cable included in your FortiGate package
- a network cable
- prior configuration of the operating mode, network interface, and static route (for details, see)

## To enable SSH or Telnet access to the CLI using a local console connection

1. Using the network cable, connect the FortiGate unit's network port either directly to your computer's network port, or to a network through which your computer can reach the FortiGate unit.
2. Note the number of the physical network port.
3. Using a local console connection, connect and log into the CLI. For details, see [“Connecting to the CLI using a local console” on page 1405](#).

4. Enter the following command:

```
config system interface
    edit <interface_str>
        set allowaccess <protocols_list>
    next
end
```

where:

- <interface\_str> is the name of the network interface associated with the physical network port and containing its number, such as port1
- <protocols\_list> is the complete, space-delimited list of permitted administrative access protocols, such as https ssh telnet

For example, to exclude HTTP, HTTPS, SNMP, and PING, and allow only SSH and Telnet administrative access on port1:

```
set system interface port1 config allowaccess ssh telnet
```

5. To confirm the configuration, enter the command to display the network interface's settings.

```
get system interface <interface_str>
```

The CLI displays the settings, including the allowed administrative access protocols, for the network interfaces.

To connect to the CLI through the network interface, see [“Connecting to the CLI using SSH” on page 1407](#) or [“Connecting to the CLI using Telnet” on page 1408](#).

## Connecting to the CLI using SSH

Once the FortiGate unit is configured to accept SSH connections, you can use an SSH client on your management computer to connect to the CLI.

Secure Shell (SSH) provides both secure authentication and secure communications to the CLI. FortiGate units support 3DES and Blowfish encryption algorithms for SSH.

Before you can connect to the CLI using SSH, you must first configure a network interface to accept SSH connections. For details, see [“Enabling access to the CLI through the network \(SSH or Telnet\)” on page 1406](#). The following procedure uses PuTTY. Steps may vary with other SSH clients.

### To connect to the CLI using SSH

1. On your management computer, start an SSH client.
2. In *Host Name (or IP Address)*, enter the IP address of a network interface on which you have enabled SSH administrative access.
3. In *Port*, enter 22.
4. For the *Connection type*, select *SSH*.
5. Select *Open*.

The SSH client connects to the FortiGate unit.

The SSH client may display a warning if this is the first time you are connecting to the FortiGate unit and its SSH key is not yet recognized by your SSH client, or if you have previously connected to the FortiGate unit but used a different IP address or SSH key. This is normal. If your management computer is directly connected to the FortiGate unit with no network hosts between them.

6. Click Yes to verify the fingerprint and accept the FortiGate unit's SSH key. You will not be able to log in until you have accepted the key.
7. The CLI displays a login prompt.
8. Type a valid administrator account name (such as `admin`) and press Enter.
9. Type the password for this administrator account and press Enter.

The FortiGate unit displays a command prompt (its host name followed by a #) . You can now enter CLI commands.

If three incorrect login or password attempts occur in a row, you will be disconnected. If this occurs, wait one minute, then reconnect to attempt the login again.

---

### Connecting to the CLI using Telnet

Once the FortiGate unit is configured to accept Telnet connections, you can use a Telnet client on your management computer to connect to the CLI.

Telnet is not a secure access method. SSH should be used to access the CLI from the Internet or any other untrusted network.

---

Before you can connect to the CLI using Telnet, you must first configure a network interface to accept SSH connections. For details, see [“Enabling access to the CLI through the network \(SSH or Telnet\)” on page 1406](#).

### To connect to the CLI using Telnet

1. On your management computer, start a Telnet client.
2. Connect to a FortiGate network interface on which you have enabled Telnet.
3. Type a valid administrator account name (such as `admin`) and press Enter.

4. Type the password for this administrator account and press Enter.

The FortiGate unit displays a command prompt (its host name followed by a #) . You can now enter CLI commands.

If three incorrect login or password attempts occur in a row, you will be disconnected. If this occurs, wait one minute, then reconnect to attempt the login again.

## Command syntax

When entering a command, the command line interface (CLI) requires that you use valid syntax and conform to expected input constraints. It will reject invalid commands.

Fortinet documentation uses the following conventions to describe valid command syntax

### Terminology

Each command line consists of a command word that is usually followed by words for the configuration data or other specific item that the command uses or affects:

```
get system admin
```

To describe the function of each word in the command line, especially if that nature has changed between firmware versions, Fortinet uses terms with the following definitions.

**Figure 225:**Command syntax terminology

- **command** — A word that begins the command line and indicates an action that the FortiGate unit should perform on a part of the configuration or host on the network, such as `config` or `execute`. Together with other words, such as fields or values, that end when you press the Enter key, it forms a command line. Exceptions include multiline command lines, which can be entered using an escape sequence. (See [“Shortcuts and key commands” on page 1416.](#))  
Valid command lines must be unambiguous if abbreviated. (See [“Command abbreviation” on page 1417.](#)) Optional words or other command line permutations are indicated by syntax notation. (See [“Notation” on page 1410.](#))
- **sub-command** — A kind of command that is available only when nested within the scope of another command. After entering a command, its applicable sub-commands are available to you until you exit the scope of the command, or until you descend an additional level into

another sub-command. Indentation is used to indicate levels of nested commands. (See [“Indentation” on page 1410.](#))

Not all top-level commands have sub-commands. Available sub-commands vary by their containing scope. (See [“Sub-commands” on page 1412.](#))

- **object** — A part of the configuration that contains tables and/or fields. Valid command lines must be specific enough to indicate an individual object.
- **table** — A set of fields that is one of possibly multiple similar sets which each have a name or number, such as an administrator account, policy, or network interface. These named or numbered sets are sometimes referenced by other parts of the configuration that use them. (See [“Notation” on page 1410.](#))
- **field** — The name of a setting, such as `ip` or `hostname`. Fields in some tables must be configured with values. Failure to configure a required field will result in an invalid object configuration error message, and the FortiGate unit will discard the invalid table.
- **value** — A number, letter, IP address, or other type of input that is usually your configuration setting held by a field. Some commands, however, require multiple input values which may not be named but are simply entered in sequential order in the same command line. Valid input types are indicated by constraint notation. (See [“Notation” on page 1410.](#))
- **option** — A kind of value that must be one or more words from of a fixed set of options. (See [“Notation” on page 1410.](#))

## Indentation

Indentation indicates levels of nested commands, which indicate what other subcommittees are available from within the scope. For example, the `edit` sub-command is available only within a command that affects tables, and the `next` sub-command is available only from within the `edit` sub-command:

```
config system interface
    edit port1
        set status up
        next
    end
```

For information about available sub-commands, see [“Sub-commands” on page 1412.](#)

## Notation

Brackets, braces, and pipes are used to denote valid permutations of the syntax. Constraint notations, such as `<address_ipv4>`, indicate which data types or string patterns are acceptable value input.

**Table 60:** Command syntax notation

Convention	Description
<b>Square brackets</b> [ ]	A non-required word or series of words. For example:  <code>[verbose {1   2   3}]</code>  indicates that you may either omit or type both the <code>verbose</code> word and its accompanying option, such as <code>verbose 3</code> .

**Table 60:** Command syntax notation

<b>Angle brackets</b> < >	<p>A word constrained by data type. The angled brackets contain a descriptive name followed by an underscore ( _ ) and suffix that indicates the valid data type. For example, &lt;retries_int&gt;, indicates that you should enter a number of retries, such as 5.</p> <p>Data types include:</p> <ul style="list-style-type: none"> <li>• &lt;xxx_name&gt;: A name referring to another part of the configuration, such as policy_A.</li> <li>• &lt;xxx_index&gt;: An index number referring to another part of the configuration, such as 0 for the first static route.</li> <li>• &lt;xxx_pattern&gt;: A regular expression or word with wild cards that matches possible variations, such as *@example.com to match all email addresses ending in @example.com.</li> <li>• &lt;xxx_fqdn&gt;: A fully qualified domain name (FQDN), such as mail.example.com.</li> <li>• &lt;xxx_email&gt;: An email address, such as admin@example.com.</li> <li>• &lt;xxx_ipv4&gt;: An IPv4 address, such as 192.168.1.99.</li> <li>• &lt;xxx_v4mask&gt;: A dotted decimal IPv4 netmask, such as 255.255.255.0.</li> <li>• &lt;xxx_ipv4mask&gt;: A dotted decimal IPv4 address and netmask separated by a space, such as 192.168.1.99 255.255.255.0.</li> <li>• &lt;xxx_ipv4/mask&gt;: A dotted decimal IPv4 address and CIDR-notation netmask separated by a slash, such as 192.168.1.1/24.</li> <li>• &lt;xxx_ipv4range&gt;: A hyphen ( - )-delimited inclusive range of IPv4 addresses, such as 192.168.1.1-192.168.1.255.</li> <li>• &lt;xxx_ipv6&gt;: A colon ( : )-delimited hexadecimal IPv6 address, such as 3f2e:6a8b:78a3:0d82:1725:6a2f:0370:6234.</li> <li>• &lt;xxx_v6mask&gt;: An IPv6 netmask, such as /96.</li> <li>• &lt;xxx_ipv6mask&gt;: A dotted decimal IPv6 address and netmask separated by a space.</li> <li>• &lt;xxx_str&gt;: A string of characters that is not another data type, such as P@ssw0rd. Strings containing spaces or special characters must be surrounded in quotes or use escape sequences. See <a href="#">“Special characters” on page 1418</a>.</li> <li>• &lt;xxx_int&gt;: An integer number that is <b>not</b> another data type, such as 15 for the number of minutes.</li> </ul>
<b>Curly braces</b> { }	<p>A word or series of words that is constrained to a set of options delimited by either vertical bars or spaces. You must enter at least one of the options, unless the set of options is surrounded by square brackets [ ].</p>

**Table 60:** Command syntax notation

<b>Options delimited by vertical bars  </b>	Mutually exclusive options. For example: <code>{enable   disable}</code> indicates that you must enter either <code>enable</code> or <code>disable</code> , but must not enter both.
<b>Options delimited by spaces</b>	Non-mutually exclusive options. For example: <code>{http https ping snmp ssh telnet}</code> indicates that you may enter all or a subset of those options, in any order, in a space-delimited list, such as: <code>ping https ssh</code>

## Sub-commands

Each command line consists of a command word that is usually followed by words for the configuration data or other specific item that the command uses or affects:

```
get system admin
```

Sub-commands are available from within the scope of some commands. When you enter a sub-command level, the command prompt changes to indicate the name of the current command scope. For example, after entering:

```
config system admin
```

the command prompt becomes:

```
(admin) #
```

Applicable sub-commands are available to you until you exit the scope of the command, or until you descend an additional level into another sub-command.

For example, the `edit` sub-command is available only within a command that affects tables; the `next` sub-command is available only from within the `edit` sub-command:

```
config system interface
  edit port1
    set status up
  next
end
```

Sub-command scope is indicated by indentation. See [“Indentation” on page 1410](#).

Available sub-commands vary by command. From a command prompt within `config`, two types of sub-commands might become available:

- commands affecting fields
- commands affecting tables

**Table 61:** Commands for tables

<b><i>clone &lt;table&gt;</i></b>	<p>Clone (or make a copy of) a table from the current object.</p> <p>For example, in <code>config firewall policy</code>, you could enter the following command to clone security policy 27 to create security policy 30:</p> <pre>clone 27 to 30</pre> <p>In <code>config antivirus profile</code>, you could enter the following command to clone an antivirus profile named <code>av_pro_1</code> to create a new antivirus profile named <code>av_pro_2</code>:</p> <pre>clone av_pro_1 to av_pro_2</pre> <p><code>clone</code> may not be available for all tables.</p>
<b><i>delete &lt;table&gt;</i></b>	<p>Remove a table from the current object.</p> <p>For example, in <code>config system admin</code>, you could delete an administrator account named <code>newadmin</code> by typing <code>delete newadmin</code> and pressing Enter. This deletes <code>newadmin</code> and all its fields, such as <code>newadmin</code>'s first-name and email-address.</p> <p><code>delete</code> is only available within objects containing tables.</p>
<b><i>edit &lt;table&gt;</i></b>	<p>Create or edit a table in the current object.</p> <p>For example, in <code>config system admin</code>:</p> <ul style="list-style-type: none"> <li>edit the settings for the default <code>admin</code> administrator account by typing <code>edit admin</code>.</li> <li>add a new administrator account with the name <code>newadmin</code> and edit <code>newadmin</code>'s settings by typing <code>edit newadmin</code>.</li> </ul> <p><code>edit</code> is an interactive sub-command: further sub-commands are available from within <code>edit</code>.</p> <p><code>edit</code> changes the prompt to reflect the table you are currently editing.</p> <p><code>edit</code> is only available within objects containing tables.</p> <p>In objects such as security policies, <code>&lt;table&gt;</code> is a sequence number. To create a new entry without the risk of overwriting an existing one, enter <code>edit 0</code>. The CLI initially confirms the creation of entry 0, but assigns the next unused number after you finish editing and enter <code>end</code>.</p>
<b><i>end</i></b>	<p>Save the changes to the current object and exit the <code>config</code> command. This returns you to the top-level command prompt.</p>
<b><i>get</i></b>	<p>List the configuration of the current object or table.</p> <ul style="list-style-type: none"> <li>In objects, <code>get</code> lists the table names (if present), or fields and their values.</li> <li>In a table, <code>get</code> lists the fields and their values.</li> </ul> <p>For more information on <code>get</code> commands, see the <a href="#">CLI Reference</a>.</p>

**Table 61:** Commands for tables

<b><i>purge</i></b>	<p>Remove all tables in the current object.</p> <p>For example, in <code>config forensic user</code>, you could type <code>get</code> to see the list of user names, then type <code>purge</code> and then <code>y</code> to confirm that you want to delete all users.</p> <p><code>purge</code> is only available for objects containing tables.</p> <p><b>Caution:</b> Back up the FortiGate unit before performing a <code>purge</code>. <code>purge</code> cannot be undone. To restore purged tables, the configuration must be restored from a backup.</p> <p><b>Caution:</b> Do not <code>purge system interface</code> or <code>system admin tables</code>. <code>purge</code> does not provide default tables. This can result in being unable to connect or log in, requiring the FortiGate unit to be formatted and restored.</p>
<b><i>rename &lt;table&gt; to &lt;table&gt;</i></b>	<p>Rename a table.</p> <p>For example, in <code>config system admin</code>, you could rename <code>admin3</code> to <code>fwadmin</code> by typing <code>rename admin3 to fwadmin</code>.</p> <p><code>rename</code> is only available within objects containing tables.</p>
<b><i>show</i></b>	<p>Display changes to the default configuration. Changes are listed in the form of configuration commands.</p>

## Example of table commands

From within the `system admin` object, you might enter:

```
edit admin_1
```

The CLI acknowledges the new table, and changes the command prompt to show that you are now within the `admin_1` table:

```
new entry 'admin_1' added
(admin_1) #
```

**Table 62:** Commands for fields

<b><i>abort</i></b>	Exit both the <code>edit</code> and/or <code>config</code> commands without saving the fields.
<b><i>append</i></b>	Add an option to an existing list.
<b><i>end</i></b>	Save the changes made to the current table or object fields, and exit the <code>config</code> command. (To exit without saving, use <code>abort</code> instead.)
<b><i>get</i></b>	<p>List the configuration of the current object or table.</p> <ul style="list-style-type: none"> <li>• In objects, <code>get</code> lists the table names (if present), or fields and their values.</li> <li>• In a table, <code>get</code> lists the fields and their values.</li> </ul>
<b><i>move</i></b>	Move an object within a list, when list order is important. For example, rearranging security policies within the policy list.

**Table 62:** Commands for fields

<b><i>next</i></b>	<p>Save the changes you have made in the current table's fields, and exit the <code>edit</code> command to the object prompt. (To save and exit completely to the root prompt, use <code>end</code> instead.)</p> <p><code>next</code> is useful when you want to create or edit several tables in the same object, without leaving and re-entering the <code>config</code> command each time.</p> <p><code>next</code> is only available from a table prompt; it is not available from an object prompt.</p>
<b><i>select</i></b>	<p>Clear all options except for those specified.</p> <p>For example, if a group contains members A, B, C, and D and you remove all users except for B, use the command <code>select member B</code>.</p>
<b><i>set &lt;field&gt; &lt;value&gt;</i></b>	<p>Set a field's value.</p> <p>For example, in <code>config system admin</code>, after typing <code>edit admin</code>, you could type <code>set password newpass</code> to change the password of the admin administrator to <code>newpass</code>.</p> <p><b>Note:</b> When using <code>set</code> to change a field containing a space-delimited list, type the whole new list. For example, <code>set &lt;field&gt; &lt;new-value&gt;</code> will replace the list with the <code>&lt;new-value&gt;</code> rather than appending <code>&lt;new-value&gt;</code> to the list.</p>
<b><i>show</i></b>	Display changes to the default configuration. Changes are listed in the form of configuration commands.
<b><i>unselect</i></b>	Remove an option from an existing list.
<b><i>unset &lt;field&gt;</i></b>	<p>Reset the table or object's fields to default values.</p> <p>For example, in <code>config system admin</code>, after typing <code>edit admin</code>, typing <code>unset password</code> resets the password of the admin administrator account to the default (in this case, no password).</p>

#### Example of field commands

From within the `admin_1` table, you might enter:

```
set password my1stExamplePassword
```

to assign the value `my1stExamplePassword` to the `password` field. You might then enter the `next` command to save the changes and edit the next administrator's table.

## Permissions

Depending on the account that you use to log in to the FortiGate unit, you may not have complete access to all CLI commands. Access profiles control which CLI commands an administrator account can access. Access profiles assign either read, write, or no access to each area of the FortiGate software. To view configurations, you must have read access. To make changes, you must have write access.

Unlike other administrator accounts, the administrator account named `admin` exists by default and cannot be deleted. The `admin` administrator account is similar to a root administrator account. This administrator account always has full permission to view and change all FortiGate configuration options, including viewing and changing **all** other administrator accounts. Its name and permissions cannot be changed. It is the only administrator account that can reset

another administrator's password without being required to enter that administrator's existing password.

Set a strong password for the admin administrator account, and change the password regularly. By default, this administrator account has no password. Failure to maintain the password of the admin administrator account could compromise the security of your FortiGate unit.

For complete access to all commands, you must log in with the administrator account named `admin`.

## Tips

Basic features and characteristics of the CLI environment provide support and ease of use for many CLI tasks.

## Help

To display brief help during command entry, press the question mark (?) key.

- Press the question mark (?) key at the command prompt to display a list of the commands available and a description of each command.
- Type a word or part of a word, then press the question mark (?) key to display a list of valid word completions or subsequent words, and to display a description of each.

## Shortcuts and key commands

**Table 63:** Shortcuts and key commands

Action	Keys
List valid word completions or subsequent words. If multiple words could complete your entry, display all possible completions with helpful descriptions of each.	?
Complete the word with the next available match. Press the key multiple times to cycle through available matches.	Tab
Recall the previous command. Command memory is limited to the current session.	Up arrow, or Ctrl + P
Recall the next command.	Down arrow, or Ctrl + N
Move the cursor left or right within the command line.	Left or Right arrow
Move the cursor to the beginning of the command line.	Ctrl + A
Move the cursor to the end of the command line.	Ctrl + E

**Table 63:** Shortcuts and key commands

Move the cursor backwards one word.	Ctrl + B
Move the cursor forwards one word.	Ctrl + F
Delete the current character.	Ctrl + D
Abort current interactive commands, such as when entering multiple lines. If you are not currently within an interactive command such as <code>config</code> or <code>edit</code> , this closes the CLI connection.	Ctrl + C
Continue typing a command on the next line for a multi-line command. For each line that you want to continue, terminate it with a backslash (\). To complete the command line, terminate it by pressing the spacebar and then the Enter key, without an immediately preceding backslash.	\ then Enter

## Command abbreviation

You can abbreviate words in the command line to their smallest number of non-ambiguous characters.

For example, the command `get system status` could be abbreviated to `g sy st`.

## Adding and removing options from lists

When adding options to a list, such as a user group, using the `set` command will remove the previous configuration. For example, if you wish to add user D to a user group that already contains members A, B, and C, the command would need to be `set member A B C D`. If only `set member D` was used, then all former members would be removed from the group.

However, there are additional commands which can be used instead of `set` for changing options in a list.

**Table 64:** Additional commands for lists

<b><i>append</i></b>	Add an option to an existing list.  For example, <code>append member</code> would add user D to a user group while all previous group members are retained
<b><i>select</i></b>	Clear all options except for those specified.  For example, if a group contains members A, B, C, and D and you remove all users except for B, use the command <code>select member B</code> .
<b><i>unselect</i></b>	Remove an option from an existing list.  For example, <code>unselect member A</code> would remove member A from a group will all previous group members are retained.

## Environment variables

The CLI supports the following environment variables. Variable names are case-sensitive.

**Table 65:** Environment variables

<b>\$USERFROM</b>	The management access type ( <code>ssh</code> , <code>telnet</code> , <code>jsconsole</code> for the <i>CLI Console</i> widget in the web-based manager, and so on) and the IP address of the administrator that configured the item.
<b>\$USERNAME</b>	The account name of the administrator that configured the item.
<b>\$SerialNum</b>	The serial number of the FortiGate unit.

For example, the FortiGate unit's host name can be set to its serial number.

```
config system global
    set hostname $SerialNum
end
```

As another example, you could log in as `admin1`, then configure a restricted secondary administrator account for yourself named `admin2`, whose `first-name` is `admin1` to indicate that it is another of your accounts:

```
config system admin
    edit admin2
        set first-name $USERNAME
```

## Special characters

The characters `<`, `>`, `(,)`, `#`, `'`, and `"` are not permitted in most CLI fields. These characters are special characters, also known as reserved characters.

You may be able to enter special character as part of a string's value by using a special command, enclosing it in quotes, or preceding it with an escape sequence — in this case, a backslash (`\`) character.

In other cases, different keystrokes are required to input a special character. If you need to enter `?` as part of config, you first need to input CTRL-V. If you enter the question mark (`?`) without first using CTRL-V, the question mark has a different meaning in CLI: it will show available command options in that section.

For example, if you enter `?` without CTRL-V:

```
edit "*.xe
token line: Unmatched double quote.
```

If you enter `?` with CTRL-V:

```
edit "*.xe?"
new entry '*.xe?' added
```

**Table 66:** Entering special characters

Character	Keys
<code>?</code>	Ctrl + V then <code>?</code>
Tab	Ctrl + V then Tab

**Table 66:** Entering special characters

Space (to be interpreted as part of a string value, not to end the string)	Enclose the string in quotation marks: "Security Administrator".  Enclose the string in single quotes: 'Security Administrator'.  Precede the space with a backslash: Security\ Administrator.
' (to be interpreted as part of a string value, not to end the string)	\'
" (to be interpreted as part of a string value, not to end the string)	\"
\	\\

## Using grep to filter get and show command output

In many cases, the `get` and `show` (and `diagnose`) commands may produce a large amount of output. If you are looking for specific information in a large `get` or `show` command output, you can use the `grep` command to filter the output to only display what you are looking for. The `grep` command is based on the standard UNIX `grep`, used for searching text output based on regular expressions.

Use the following command to display the MAC address of the FortiGate unit internal interface:

```
get hardware nic internal | grep Current_HWaddr
Current_HWaddr                00:09:0f:cb:c2:75
```

Use the following command to display all TCP sessions in the session list and include the session list line number in the output

```
get system session list | grep -n tcp
```

Use the following command to display all lines in HTTP replacement message commands that contain URL (upper or lower case):

```
show system replacemsg http | grep -i url
```

There are three additional options that can be applied to `grep`:

```
-A <num> After
-B <num> Before
-C <num> Context
```

The option `-f` is also available to support Fortinet contextual output, in order to show the complete configuration. The following example shows the difference in output when `-f` option is used versus when it is not.

**Using -f:**

```
show | grep -f ldap-group1
config user group
    edit "ldap-group1"
        set member "pc40-LDAP"
    next
end
config firewall policy
    edit 2
        set srcintf "port31"
        set dstintf "port32"
        set srcaddr "all"
        set action accept
        set identity-based enable
        set nat enable
        config identity-based-policy
            edit 1
                set schedule "always"
                set groups "ldap-group1"
                set dstaddr "all"
                set service "ALL"
            next
        end
    next
end
```

**Without using -f:**

```
show | grep ldap-group1
    edit "ldap-group1"
        set groups "ldap-group1"
```

## Language support and regular expressions

Characters such as ñ, é, symbols, and ideographs are sometimes acceptable input. Support varies by the nature of the item being configured. CLI commands, objects, field names, and options must use their exact ASCII characters, but some items with arbitrary names or values may be input using your language of choice. To use other languages in those cases, you must use the correct encoding.

Input is stored using Unicode UTF-8 encoding but is not normalized from other encodings into UTF-8 before it is stored. If your input method encodes some characters differently than in UTF-8, your configured items may not display or operate as expected.

Regular expressions are especially impacted. Matching uses the UTF-8 character values. If you enter a regular expression using another encoding, or if an HTTP client sends a request in an encoding other than UTF-8, matches may not be what you expect.

For example, with Shift-JIS, backslashes ( \ ) could be inadvertently interpreted as the symbol for the Japanese yen ( ¥ ) and vice versa. A regular expression intended to match HTTP requests containing money values with a yen symbol therefore may not work if the symbol is entered using the wrong encoding.

For best results, you should:

- use UTF-8 encoding, or
- use only the characters whose numerically encoded values are the same in UTF-8, such as the US-ASCII characters that are also encoded using the same values in ISO 8859-1, Windows code page 1252, Shift-JIS and other encodings, or
- for regular expressions that must match HTTP requests, use the same encoding as your HTTP clients.

HTTP clients may send requests in encodings other than UTF-8. Encodings usually vary by the client's operating system or input language. If you cannot predict the client's encoding, you may only be able to match any parts of the request that are in English, because regardless of the encoding, the values for English characters tend to be encoded identically. For example, English words may be legible regardless of interpreting a web page as either ISO 8859-1 or as GB2312, whereas simplified Chinese characters might only be legible if the page is interpreted as GB2312.

---

If you configure your FortiGate unit using other encodings, you may need to switch language settings on your management computer, including for your web browser or Telnet/SSH client. For instructions on how to configure your management computer's operating system language, locale, or input method, see its documentation.

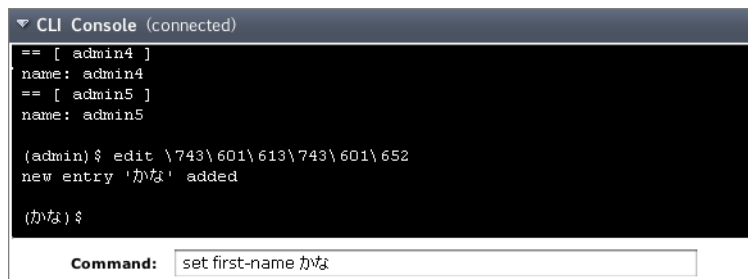

If you choose to configure parts of the FortiGate unit using non-ASCII characters, verify that all systems interacting with the FortiGate unit also support the same encodings. You should also use the same encoding throughout the configuration if possible in order to avoid needing to switch the language settings of the web-based manager and your web browser or Telnet/SSH client while you work.

Similarly to input, your web browser or CLI client should usually interpret display output as encoded using UTF-8. If it does not, your configured items may not display correctly in the web-based manager or CLI. Exceptions include items such as regular expressions that you may have configured using other encodings in order to match the encoding of HTTP requests that the FortiGate unit receives.

### **To enter non-ASCII characters in the CLI Console widget**

1. On your management computer, start your web browser and go to the URL for the FortiGate unit's web-based manager.
2. Configure your web browser to interpret the page as UTF-8 encoded.
3. Log in to the FortiGate unit.
4. Go to *System > Dashboard > Status*.
5. In title bar of the *CLI Console* widget, click *Edit* (the pencil icon).
6. Enable *Use external command input box*.
7. Select *OK*.
8. The *Command* field appears below the usual input and display area of the *CLI Console* widget.
9. In *Command*, type a command.

**Figure 226:**Entering encoded characters (*CLI Console* widget)

```
CLI Console (connected)
== [ admin4 ]
name: admin4
== [ admin5 ]
name: admin5

(admin)$ edit \743\601\613\743\601\652
new entry 'かな' added

(かな)$

Command: set first-name かな
```

**10. Press Enter.**

In the display area, the *CLI Console* widget displays your previous command interpreted into its character code equivalent, such as:

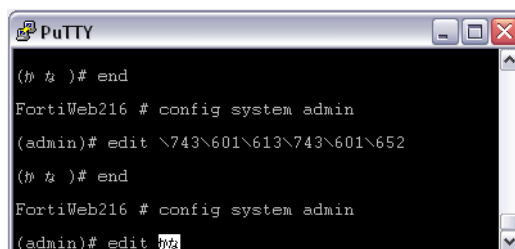

```
edit \743\601\613\743\601\652
```

and the command's output.

**To enter non-ASCII characters in a Telnet/SSH client**

1. On your management computer, start your Telnet or SSH client.
2. Configure your Telnet or SSH client to send and receive characters using UTF-8 encoding.  
Support for sending and receiving international characters varies by each Telnet/SSH client. Consult the documentation for your Telnet/SSH client.
3. Log in to the FortiGate unit.
4. At the command prompt, type your command and press Enter.

**Figure 227:**Entering encoded characters (PuTTY)

```
PuTTY
(かな)# end
FortiWeb216 # config system admin
(admin)# edit \743\601\613\743\601\652
(かな)# end
FortiWeb216 # config system admin
(admin)# edit \743\601\613\743\601\652
```

You may need to surround words that use encoded characters with single quotes ( ' ).

Depending on your Telnet/SSH client's support for your language's input methods and for sending international characters, you may need to interpret them into character codes before pressing Enter.

For example, you might need to enter:

```
edit '\743\601\613\743\601\652'
```

5. The CLI displays your previous command and its output.

## Screen paging

You can configure the CLI to pause after displaying each page's worth of text when displaying multiple pages of output. When the display pauses, the last line displays `--More--`. You can then either:

- press the spacebar to display the next page.
- type `Q` to truncate the output and return to the command prompt.

This may be useful when displaying lengthy output, such as the list of possible matching commands for command completion, or a long list of settings. Rather than scrolling through or possibly exceeding the buffer of your terminal emulator, you can simply display one page at a time.

To configure the CLI display to pause when the screen is full:

```
config system console
    set output more
end
```

## Baud rate

You can change the default baud rate of the local console connection.

To change the baud rate enter the following commands:

```
config system console
    set baudrate {115200 | 19200 | 38400 | 57600 | 9600}
end
```

## Editing the configuration file on an external host

You can edit the FortiGate configuration on an external host by first backing up the configuration file to a TFTP server. Then edit the configuration file and restore it to the FortiGate unit.

Editing the configuration on an external host can be timesaving if you have many changes to make, especially if your plain text editor provides advanced features such as batch changes.

### To edit the configuration on your computer

1. Use `execute backup` to download the configuration file to a TFTP server, such as your management computer.
2. Edit the configuration file using a plain text editor that supports Unix-style line endings.

Do not edit the first line. The first line(s) of the configuration file (preceded by a # character) contains information about the firmware version and FortiGate model. If you change the model number, the FortiGate unit will reject the configuration file when you attempt to restore it.

---

3. Use `execute restore` to upload the modified configuration file back to the FortiGate unit. The FortiGate unit downloads the configuration file and checks that the model information is correct. If it is, the FortiGate unit loads the configuration file and checks each command for errors. If a command is invalid, the FortiGate unit ignores the command. If the configuration file is valid, the FortiGate unit restarts and loads the new configuration.

## Using Perl regular expressions

Some FortiGate features, such as spam filtering and web content filtering can use either wildcards or Perl regular expressions.

See <http://perldoc.perl.org/perlretut.html> for detailed information about using Perl regular expressions. For more information on using Perl expressions see the [Security Profiles](#) chapter of *The Handbook*.

## Differences between regular expression and wildcard pattern matching

In Perl regular expressions, the period (‘.’) character refers to any single character. It is similar to the question mark (‘?’) character in wildcard pattern matching. As a result:

- `example.com` not only matches `example.com` but also matches `exampleacom`, `examplebcom`, `exampleccom` and so on.

To match a special character such as the period (‘.’) and the asterisk (‘\*’), regular expressions use the slash (‘\’) escape character. For example:

- To match `example.com`, the regular expression should be `example\.com`.

In Perl regular expressions, the asterisk (‘\*’) means match 0 or more times of the character before it, not 0 or more times of any character. For example:

- `exam*.com` matches `exammm.com` but does not match `example.com`.

To match any character 0 or more times, use ‘.\*’ where ‘.’ means any character and the ‘\*’ means 0 or more times. For example:

- the wildcard match pattern `exam*.com` is equivalent to the regular expression `exam.*\.com`.

## Word boundary

In Perl regular expressions, the pattern does not have an implicit word boundary. For example, the regular expression “test” not only matches the word “test” but also matches any word that contains the word “test” such as “atest”, “mytest”, “testimony”, “atestb”. The notation “\b” specifies the word boundary. To match exactly the word “test”, the expression should be `\btest\b`.

## Case sensitivity

Regular expression pattern matching is case sensitive in the Web and Spam filters. To make a word or phrase case insensitive, use the regular expression `/i`. For example, `/bad language/i` will block all instances of “bad language” regardless of case.

**Table 67:** Perl regular expression examples

Expression	Matches
<b>abc</b>	abc (that exact character sequence, but anywhere in the string)
<b>^abc</b>	abc at the beginning of the string
<b>abc\$</b>	abc at the end of the string
<b>a b</b>	either of a and b
<b>^abc abc\$</b>	the string abc at the beginning or at the end of the string
<b>ab{2,4}c</b>	an a followed by two, three or four b's followed by a c
<b>ab{2,}c</b>	an a followed by at least two b's followed by a c
<b>ab*c</b>	an a followed by any number (zero or more) of b's followed by a c
<b>ab+c</b>	an a followed by one or more b's followed by a c
<b>ab?c</b>	an a followed by an optional b followed by a c; that is, either abc or ac
<b>a.c</b>	an a followed by any single character (not newline) followed by a c

**Table 67:** Perl regular expression examples

<b>a\.c</b>	a.c exactly
<b>[abc]</b>	any one of a, b and c
<b>[Aa]bc</b>	either of Abc and abc
<b>[abc]+</b>	any (nonempty) string of a's, b's and c's (such as a, abba, acbabcacaa)
<b>[^abc]+</b>	any (nonempty) string which does not contain any of a, b and c (such as defg)
<b>\d\d</b>	any two decimal digits, such as 42; same as \d{2}
<b>/i</b>	makes the pattern case insensitive. For example, /bad language/i blocks any instance of "bad language" regardless of case.
<b>\w+</b>	a "word": a nonempty sequence of alphanumeric characters and low lines (underscores), such as foo and 12bar8 and foo_1
<b>100\s*mk</b>	the strings 100 and mk optionally separated by any amount of white space (spaces, tabs, newlines)
<b>abc\b</b>	abc when followed by a word boundary (e.g. in abc! but not in abcd)
<b>perl\b</b>	perl when not followed by a word boundary (e.g. in perlert but not in perl stuff)
<b>\x</b>	tells the regular expression parser to ignore white space that is neither backslashed nor within a character class. You can use this to break up your regular expression into (slightly) more readable parts.

# Basic Administration

The FortiGate unit requires some basic configuration to add it to your network. These basic steps include assigning IP addresses, adding routing, and configuring security policies. Until the administrator completes these steps, inter-network and Internet traffic will not flow through the unit.

There are two methods of configuring the FortiGate unit: the web-based manager or the command line interface (CLI). This chapter will step through both methods to complete the basic configurations to put the device on your network. Use whichever you are most comfortable with.

This chapter also provides guidelines for password and administrator best practices as well as how to upgrade the firmware.

This section includes the topics:

- [Connecting to the FortiGate unit](#)
- [System configuration](#)
- [Passwords](#)
- [Administrators](#)
- [Configuration backups](#)
- [Firmware](#)
- [Controlled upgrade](#)

For setup and configuration of your specific FortiGate models, see the [QuickStart Guide](#) for that model.

## Connecting to the FortiGate unit

To configure, maintain and administer the FortiGate unit, you need to connect to it from a management computer. There are two ways to do this:

- using the web-based manager: a GUI interface that you connect to using a current web browser, such as Firefox or Internet Explorer.
- using the command line interface (CLI): a command line interface similar to DOS or UNIX commands that you connect to using SSH or a Telnet terminal.

### Connecting to the web-based manager

To connect to the web-based manager, you require:

- a computer with an Ethernet connection
- Microsoft Internet Explorer version 6.0 or higher or any recent version of a common web browser
- an Ethernet cable.

### To connect to the web-based manager

1. Set the IP address of the management computer to the static IP address 192.168.1.2 with a netmask of 255.255.255.0.
2. Using the Ethernet cable, connect the internal or port 1 interface of the FortiGate unit to the computer Ethernet connection.
3. Start your browser and enter the address `https://192.168.1.99`. (remember to include the “s” in `https://`).

To support a secure HTTPS authentication method, the FortiGate unit ships with a self-signed security certificate that is offered to remote clients whenever they initiate a HTTPS connection to the FortiGate unit. When you connect, the FortiGate unit displays two security warnings in a browser.

The first warning prompts you to accept and optionally install the FortiGate unit's self-signed security certificate. If you do not accept the certificate, the FortiGate unit refuses the connection. If you accept the certificate, the FortiGate login page appears. The credentials entered are encrypted before they are sent to the FortiGate unit. If you choose to accept the certificate permanently, the warning is not displayed again.

Just before the FortiGate login page is displayed, a second warning informs you that the FortiGate certificate distinguished name differs from the original request. This warning occurs because the FortiGate unit redirects the connection. This is an informational message. Select *OK* to continue logging in.

4. Type `admin` in the Name field and select *Login*.

## Connecting to the CLI

The command line interface (CLI) is an alternative method of configuring the FortiGate unit. The CLI compliments the web-based manager in that it not only has the same configuration options, but also contains additional settings not available through the web-based manager.

If you are new to FortiOS or a command line interface configuration tool, see [“Using the CLI” on page 1405](#) for an overview of the CLI, how to connect to it, and how to use it.

## System configuration

Once the FortiGate unit is connected and traffic can pass through, several more configuration options are available. While not mandatory, they will help to ensure better control with the firewall.

### Setting the time and date

For effective scheduling and logging, the FortiGate system date and time should be accurate. You can either manually set the system date and time or configure the FortiGate unit to automatically keep its time correct by synchronizing with a Network Time Protocol (NTP) server.

#### To set the date and time - web-based manager

1. Go to *System > Dashboard > Status*.
2. Under *System Information > System Time*, select *Change*.
3. Select your *Time Zone*.
4. Select *Set Time* and set the FortiGate system date and time.
5. Select *OK*.

## Set the time and date - CLI

```
config system global
    set timezone <zone_value>
end
execute date [<date_str>]
execute time [<time_str>]
```

By default, FortiOS has the daylight savings time configuration enabled. The system time must be manually adjusted after daylight saving time ends. To disable DST, enter the following command in the CLI:

```
config system global
    set dst disable
end
```

## Using the NTP Server

The Network Time Protocol enables you to keep the FortiGate time in sync with other network systems. By enabling NTP on the FortiGate unit, FortiOS will check with the NTP server you select at the configured intervals. This will also ensure that logs and other time-sensitive settings on the FortiGate unit are correct.

The FortiGate unit maintains its internal clock using a built-in battery. At startup, the time reported by the FortiGate unit will indicate the hardware clock time, which may not be accurate. When using NTP, the system time might change after the FortiGate has successfully obtained the time from a configured NTP server.

For the NTP server, you can identify a specific port/IP address for this self-originating traffic. The configuration is performed in the CLI with the command `set source-ip`. For example, to set the source IP of NTP to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config system ntp
    set ntpsyn enable
    set syncinterval 5
    set source-ip 192.168.4.5
end
```

## Configuring FortiGuard

FortiGuard is Fortinet's threat research and response team. With more than 200 security engineers and forensic analysts around the globe providing 24 hours a day, 365 days a year analysis of current threats on the Internet, the FortiGuard team's sole purpose is to protect customers.

The FortiGuard Distribution Network (FDN) is a world-wide network of FortiGuard Distribution Servers (FDS). When the FortiGate unit connects to the FDN, it connects to the nearest FDS. To do this, all FortiGate units are programmed with a list of FDS addresses sorted by nearest time zone according to the time zone configured for the FortiGate unit.

Before you can begin receiving updates, you must register your FortiGate unit from the Fortinet webpage. After registering, you need to configure the FortiGate unit to connect to the FDN to update antivirus, antispam, and IPS attack definitions.

## Updating antivirus and IPS definitions

After you have registered your FortiGate unit, you can update the definitions for antivirus and IPS. The FortiGuard Center enables you to receive push updates, allow push update to a specific IP address, and schedule updates for daily, weekly, or hourly intervals.

### To update antivirus definitions and IPS signatures

1. Go to *System > Config > FortiGuard*.
2. Select the expand arrow for *AV and IPS Options*.
3. Select *Update Now* to update the antivirus definitions.

If the connection to the FDN is successful, the web-based manager displays a message similar to the following:

Your update request has been sent. Your database will be updated in a few minutes. Please check your update page for the status of the update.

After a few minutes, if an update is available, the FortiGuard Center Services information on the Dashboard lists new version information for antivirus definitions. The System Status page also displays new dates and version numbers for the antivirus definitions. Messages are recorded to the event log indicating whether or not the update was successful or not.

Updating antivirus definitions can cause a very short disruption in traffic currently being scanned while the FortiGate unit applies the new signature database. Schedule updates when traffic is light, for example overnight, to minimize any disruption.

## Passwords

The FortiGate unit ships with a default admin account that has no password. You will want to apply a password to prevent anyone from logging into the FortiGate unit and changing configuration options.

### To change the administrator password - web-based manager

1. Go to *System > Admin > Administrators*.
2. Select the admin account and select *Change Password*.
3. Enter a new password and select *OK*.

### Set the admin password - CLI

```
config system admin
  edit admin
    set password <admin_password>
  end
```

## Password considerations

When changing the password, consider the following to ensure better security.

- Do not make passwords that are obvious, such as the company name, administrator names, or other obvious word or phrase.
- Use numbers in place of letters, for example, `passw0rd`. Alternatively, spell words with extra letters, for example, `password`.
- Administrative passwords can be up to 64 characters.

- Include a mixture of letters, numbers, and upper and lower case.
- Use multiple words together, or possibly even a sentence, for example keytothehighway.
- Use a password generator.
- Change the password regularly and always make the new password unique and not a variation of the existing password, such as changing from password to password1.
- Write the password down and store it in a safe place away from the management computer, in case you forget it or ensure that at least two people know the password in the event that one person becomes ill, is away on vacation or leaves the company. Alternatively, have two different admin logins.

## Password policy

The FortiGate unit includes the ability to enforce a password policy for administrator login. With this policy, you can enforce regular changes and specific criteria for a password including:

- minimum length between 8 and 64 characters.
- if the password must contain uppercase (A, B, C) and/or lowercase (a, b, c) characters.
- if the password must contain numbers (1, 2, 3).
- if the password must contain non-alphanumeric characters (!, @, #, \$, %, ^, &, \*, (),).
- where the password applies (admin or IPsec or both).
- the duration of the password before a new one must be specified.

### To apply a password policy - web-based manager

1. Go to *System > Admin > Settings*.
2. Select *Enable Password Policy* and configure the settings as required.

### To apply a password policy - CLI

```
config system password-policy
    set status enable
```

Configure the other settings as required.

If you add a password policy or change the requirements on an existing policy, the next time that administrator logs into the FortiGate unit, they are prompted to update their password to meet the new requirements before proceeding to log in.

**Figure 228:** Password policy dialog box

**Your password does not conform to the password policy, please input a new password.**

New Password:  ?

Confirm Password:

OK Cancel

**Password Policy**

Minimum Length:	15 Characters
Must Contain:	1 Upper Case Letters

## Lost Passwords

If an administrator password has been lost, refer to the SysAdmin's Notebook article "Resetting a lost admin password," found at [docs.fortinet.com/p/sysadmin-s-notebook-and-tech-notes](https://docs.fortinet.com/p/sysadmin-s-notebook-and-tech-notes).

## Administrators

By default, the FortiGate unit has a super administrator called "admin". This user login cannot be deleted and always has ultimate access over the FortiGate unit. Additional administrators can be added for various functions, each with a unique username, password, and set of access privileges.

There are two levels of administrator accounts; regular administrators and system administrators. Regular administrators are administrators with any admin profile other than the default super\_admin. System administrators are administrators that are assigned the super\_admin profile, which has the highest level of access.

### Adding administrators

The name of the administrator should not contain the characters < > ( ) # " ' . Using these characters in the administrator account name can result in a cross site scripting (XSS) vulnerability.

Only the default "admin" account or an administrator with read-write access control to add new administrator accounts and control their permission levels can create a new administrator account. If you log in with an administrator account that does not have the super\_admin admin profile, the administrators list will show only the administrators for the current virtual domain.

When adding administrators, you are setting up the administrator's user account. An administrator account comprises of an administrator's basic settings as well as their access profile. The access profile is a definition of what the administrator is capable of viewing and editing.

#### To add an administrator - web-based manager

1. Go to *System > Admin > Administrators*.
2. Select *Create New*.
3. Enter the administrator name.
4. Select the type of account it will be. If you select *Remote*, the FortiGate unit can reference a RADIUS, LDAP or TACAS+ server.
5. When selecting *Remote* or *PKI* accounts, select the User Group the account will access.  
For information on logging in using remote authentication servers, see the [User Authentication Guide](#). For an example of setting up a user with LDAP, see "LDAP Admin Access and Authorization" on page 1432
6. Enter the password for the user.  
This may be a temporary password that the administrator can change later. Passwords can be up to 256 characters in length. For more information on passwords, see "Passwords" on page 1429.
7. Select *OK*.

### To add an administrator - CLI

```
config system admin
  edit <admin_name>
    set password <password>
    set accprofile <profile_name>
  end
```

## LDAP Admin Access and Authorization

You can use the LDAP server as a means to add administrative users, saving the time to add users to the FortiGate unit administrator list. After configuring, any user within the selected LDAP group server can automatically log into the FortiGate unit as an administrator. Ensure that the admin profile is the correct level of access, or the users within the LDAP group are the only ones authorized to configure or modify the configuration of the FortiGate unit.

To do this, requires three steps:

- configure the LDAP server
- add the LDAP server to a user group
- configure the administrator account

### Configure the LDAP server

First set up the LDAP server as you normally would, and include a group to bind to.

#### To configure the LDAP server - web-based manager

1. Go to *User & Device > Remote > LDAP* and select *Create New*.
2. Enter a *Name* for the server.
3. Enter the *Server IP* address or name.
4. Enter the *Common Name Identifier* and *Distinguished Name*.
5. Set the *Bind Type* to *Regular* and enter the *User DN* and *Password*.
6. Select *OK*.

#### To configure the LDAP server - CLI

```
config user ldap
  edit <ldap_server_name>
    set server <server_ip>
    set cnid cn
    set dn DC=XYZ,DC=COM
    set type regular
    set username CN=Administrator,CN=Users,DC=XYZ,DC=COM
    set password <password>
    set member-attr <group_binding>
  end
```

### Add the LDAP server to a user group

Next, create a user group that will include the LDAP server that was created above.

#### To create a user group - web-based manager

1. Go to *User & Device > User Group > User Group* and select *Create New*.
2. Enter a *Name* for the group.

3. In the section labelled *Remote authentication servers*, select *Add*.
4. Select the *Remote Server* from the drop-down list.
5. Select *OK*.

#### To create a user group - CLI

```
config user group
  edit <group_name>
    config match
      edit 1
        set server-name <LDAP_server>
        set group-name <group_name>
      end
    end
  end
```

### Configure the administrator account

Now you can create a new administrator, where rather than entering a password, you will use the new user group and the wildcard option for authentication.

#### To create an administrator - web-based manager

1. Go to *System > Admin > Administrators* and select *Create New*.
2. In the *Administrator* field, enter the name for the administrator.
3. For *Type*, select *Remote*.
4. Select the *User Group* created above from the drop-down list.
5. Select *Wildcard*.
6. The *Wildcard* option allows for LDAP users to connect as this administrator.
7. Select an *Admin Profile*.
8. Select *OK*.

#### To create an administrator - CLI

```
config system admin
  edit <admin_name>
    set remote-auth enable
    set accprofile super_admin
    set wildcard enable
    set remote-group ldap
  end
```

### Monitoring administrators

You can view the administrators logged in using the *System Information* widget on the Dashboard. On the widget is the *Current Administrator* row that shows the administrator logged in and the total logged in. Selecting *Details* displays the administrators), where they are logging in from and how (CLI, web-based manager) and when they logged in.

You are also able to monitor the activities the administrators perform on the FortiGate unit using the logging of events. Event logs include a number of options to track configuration changes.

### To set logging - web-based manager

1. Go to *Log & Report > Log Config > Log Settings*.
- 2 Under *Event Logging*, ensure *System activity event* is selected.
- 3 Select *Apply*.

### To set logging - CLI

```
config log eventfilter
    set event enable
    set system enable
end
```

To view the logs go to *Log & Report > Event Log*.

## Administrator profiles

Administer profiles define what the administrator user can do when logged into the FortiGate unit. When you set up an administrator user account, you also assign an administrator profile, which dictates what the administrator user will see. Depending on the nature of the administrator's work, access level or seniority, you can allow them to view and configure as much, or as little, as required.

### super\_admin profile

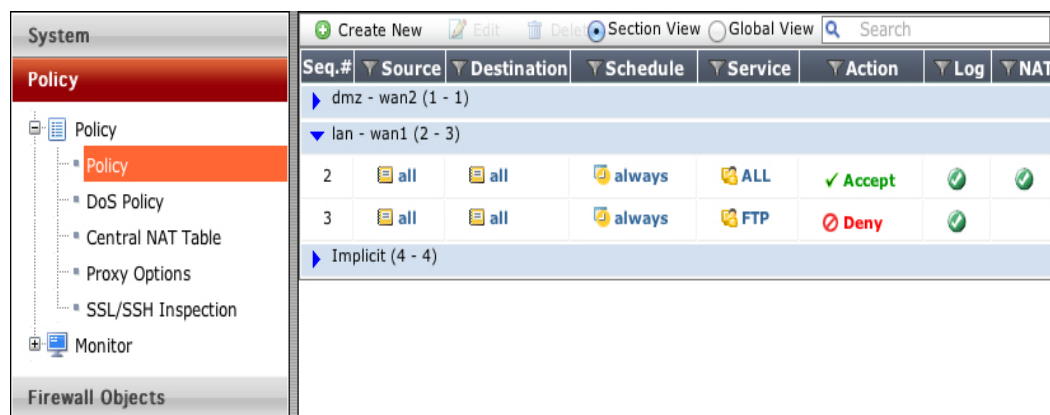

The super\_admin administrator is the administrative account that the primary administrator should have to log into the FortiGate unit. The profile can not be deleted or modified to ensure there is always a method to administer the FortiGate unit. This user profile has access to all components of FortiOS, including the ability to add and remove other system administrators. For some administrative functions, such as backing up and restoring the configuration using SCP, super\_admin access is required.

### Creating profiles

To configure administrator profiles go to *System > Admin > Admin Profiles*. You can only assign one profile to an administrator user.

On the *New Admin Profile* page, you define the components of FortiOS that will be available to view and/or edit. For example, if you configure a profile so that the administrator can only access the firewall components, when an administrator with that profile logs into the FortiGate unit, they will only be able to view and edit any firewall components including policies, addresses, schedules and any other settings that directly affect security policies.

**Figure 229:** The view of an administrator with firewall-only access

## Global and vdom profiles

By default, when you add a new administrative profile, it is set to have a vdom scope. That is, only the super\_admin has a global profile that enables configuration of the entire FortiGate unit.

There may be instances where additional global administrative profiles may be required. To add more global profiles, use the following CLI command to set or change an administrative profile to be global.

```
config system accprofile
    set scope global
    ...
end
```

Once the scope is set, you can enable the read and read/write settings.

## Regular (password) authentication for administrators

You can use a password stored on the local FortiGate unit to authenticate an administrator. When you select *Regular* for *Type*, you will see *Local* as the entry in the *Type* column when you view the list of administrators.

## Management access

Management access defines how administrators are able to log on to the FortiGate unit to perform management tasks such as configuration and maintenance. Methods of access can include local access through the console connection or remote access over a network or modem interface using various protocols including Telnet and HTTPS.

You can configure management access on any interface in your VDOM. In NAT mode, the interface IP address is used for management access. In transparent mode, you configure a single management IP address that applies to all interfaces in your VDOM that permit management access. The FortiGate unit also uses this IP address to connect to the FDN for virus and attack updates.

The system administrator (admin) can access all VDOMs, and create regular administrator accounts. A regular administrator account can access only the VDOM to which it belongs and the management computer must connect to an interface in that VDOM. In both cases, the management computer must connect to an interface that permits management access and its IP address must be on the same network. Management access can be via HTTP, HTTPS, Telnet, or SSH sessions, if those services are enabled on the interface. HTTPS and SSH are preferred as they are more secure.

You can allow remote administration of the FortiGate unit. However, allowing remote administration from the Internet could compromise the security of the FortiGate unit. You should avoid this unless it is required for your configuration. The following precautions can be taken to improve the security of a FortiGate unit that allows remote administration from the Internet:

- Use secure administrative user passwords.
- Change these passwords regularly.
- Enable two-factor authentication for administrators.
- Enable secure administrative access to this interface using only HTTPS or SSH.
- Use Trusted Hosts to limit where the remote access can originate from.
- Do not change the system idle timeout from the default value of 5 minutes.

## Security Precautions

One potential point of a security breach is at the management computer. Administrators who leave their workstations for a prolonged amount of time while staying logged into the web-based manager or CLI leave the firewall open to malicious intent.

### Change the admin username and password

The default super administrator user name, `admin`, is a very standard, making it easy for someone with malicious intent to determine or guess. Having the correct user name is one half of the key to the FortiGate unit being compromised and so the default name should be changed.

To do this, you need to create another super user with full access and log in as that user. Then go to *System > Admin > Administrator*, select the *admin* account, and select *Edit* to change the user name.

If it has not been done already, the password should also be changed at this time. For tips about changing the password, see [“Password considerations” on page 1429](#).

### Preventing unwanted login attempts

Setting trusted hosts for an administrator limits what computers an administrator can log in from, causing the FortiGate unit to only accept the administrator's login from the configured IP address. Any attempt to log in with the same credentials from any other IP address will be dropped.

Trusted hosts are configured when adding a new administrator by going to *System > Admin > Administrators* in the web-based manager or `config system admin` in the CLI.

To ensure the administrator has access from different locations, you can enter up to ten IP addresses, though ideally this should be kept to a minimum. For higher security, use an IP address with a net mask of 255.255.255.255, and enter an IP address (non-zero) in each of the three default trusted host fields. Also ensure all entries contain actual IP addresses, not the default 0.0.0.0.

The trusted hosts apply to the web-based manager, ping, snmp and the CLI when accessed through Telnet or SSH. CLI access through the console port is not affected.

### Prevent multiple admin sessions

Multiple admin sessions can occur when multiple users access the FortiGate using the same admin account. By default, the FortiGate unit enables multiple logins of administrators using the same login credentials from different locations. To control admin log ins, and minimize the potential of configuration collisions, you can disable concurrent admin sessions. When disabled, only one user can use the admin account at a time. When a second admin attempts to connect, connection is denied with a message that the login attempt failed.

**To disable concurrent admin sessions, enter the following command in the CLI:**

```
config system global
    set admin-concurrent disable
end
```

On 2U FortiGate units, this option is also available in the Web-Based Manager by going to *System > Admin > Settings* and select *Allow each admin to log in with multiple sessions*.

## Segregated administrative roles

To minimize the effect of an administrator causing errors to the FortiGate configuration and possibly jeopardizing the network, create individual administrative roles where none of the administrators have super-admin permissions. For example, one admin account is used solely to create security policies, another for users and groups, another for VPN, and so on.

## Disable admin services

On untrusted networks, turn off the weak administrative services such as Telnet and HTTP. With these services, passwords are passed in the clear, not encrypted. These services can be disabled by going to *System > Network > Interface* and unselecting the required check boxes.

## SSH login time out

When logging into the console using SSH, the default time of inactivity is 120 seconds (2 minutes) to successfully log into the FortiGate unit. To enhance security, you can configure the time to be shorter. Using the CLI, you can change the length of time the command prompt remains idle before the FortiGate unit will log the administrator out. The range can be between 10 and 3600 seconds.

**To set the logout time enter the following commands:**

```
config system global
    set admin-ssh-grace-time <number_of_seconds>
end
```

## Administrator lockout

By default, the FortiGate unit includes set number of three password retries, allowing the administrator a maximum of three attempts to log into their account before they are locked out for a set amount of time (by default, 60 seconds).

The number of attempts can be set to an alternate value, as well as the default wait time before the administrator can try to enter a password again. You can also change this to further sway would-be hackers. Both settings are must be configured with the CLI

**To configure the lockout options:**

```
config system global
    set admin-lockout-threshold <failed_attempts>
    set admin-lockout-duration <seconds>
end
```

For example, to set the lockout threshold to one attempt and a five minute duration before the administrator can try again to log in enter the commands”

```
config system global
    set admin-lockout-threshold 1
    set admin-lockout-duration 300
end
```

## Idle time-out

To avoid the possibility of an administrator walking away from the management computer and leaving it exposed to unauthorized personnel, you can add an idle time-out that will automatically log the user out if the web-based manager is not used for a specified amount of time. This will cause the administrator to log in to the device again in order to continue their work.

The time-out can be set as high as 480 minutes, or eight hours, although this is not recommend.

### To set the idle time out - web-based manager

1. Go to *System > Admin > Settings*.
2. In the *Administration Settings*, enter the amount of time the Administrator login can remain idle in the *Idle Timeout* field.
3. Select *Apply*.

### To set the idle time out - CLI

```
config system global
    set admintimeout <minutes>
end
```

## Administrative ports

You can set the web-based manager access to use HTTP, HTTPS, SSH, and Telnet. In these cases, the default ports for these protocols are 80, 443, 22, and 23 respectively. You can change the ports used for network administration to a different, unused port to further limit potential hackers.

Ensure the port you select is not a port you will be using for other applications. For a list of assigned port numbers, see <http://www.iana.org/assignments/port-numbers>.

### To change the administrative ports - web-based manager

1. Go to *System > Admin > Settings*.
2. In the *Web Administration Ports* section, change the port numbers.
3. Select *Apply*.

### To change the administrative ports - CLI

```
config system global
    set admin-port <http_port_number>
    set admin-sport <https_port_number>
    set admin-ssh-port <ssh_port_number>
    set admin-telnet-port <telnet_port_number>
end
```

When logging into the FortiGate unit, by default FortiOS will automatically use the default ports. That is, when logging into the FortiGate IP address, you only need to enter the address, for example:

```
https://192.168.1.1
```

When you change the administrative port number, the port number must be added to the url. For example, if the port number for HTTPS access is 2112, the administrator must enter the following address:

```
https://192.168.1.1:2112
```

## HTTPS redirect

When selecting port numbers for various protocols, you can also enable or disable the Redirect to HTTPS option. When enabled, if you select the Administrative Access for an interface to be

only HTTP, HTTPS will automatically be enabled, allowing the administrator access with either HTTP or HTTPS. The administrator can then log in using HTTPS for better security.

Note that if an SSL VPN is also configured for the same port, the SSL connection is over the HTTPS protocol. In these situations, the FortiGate unit will not redirect an HTTP address to the SSL VPN HTTPS address. Ideally, the administrator should not have the management address and an SSL VPN portal on the same interface.

### Log in/out warning message

For administrators logging in and out of the FortiGate unit, you can include a login disclaimer. This disclaimer provides a statement that must be accepted or declined where corporations are governed by strict usage policies for forensics and legal reasons.

The disclaimer is enabled through the CLI.

#### To disable an interface:

```
config system global
    set pre-login-banner enable
    set post-login-banner enable
end
```

When set, once the administrator enters their user name and password, the disclaimer appears. They must select either Accept or Decline to proceed. When the post login is enabled, once the administrator logs out they are presented with the same message.

The banner is a default message that you can customize by going to *System > Config > Replacement Messages*. Select *Extended View* to see the *Admin* category and messages.

### Disable the console interface

To prevent any unwanted login attempts using the COM communication port, you can disable login connections to the FortiGate unit.

This command is specifically for the COM port. You can still use FortiExplorer to connect and configure the FortiGate unit if required.

#### To disable an interface:

```
config system console
    set login disable
end
```

### Disable interfaces

If any of the interfaces on the FortiGate unit are not being used, disable traffic on that interface. This avoids someone plugging in network cables and potentially causing network bypass or loop issues.

#### To disable an interface - web-based manager

1. Go to *System > Network > Interface*.
2. Select the interface from the list and select *Edit*.
3. For *Administrative Access*, select *Down*.
4. Select *OK*.

### To disable an interface - CLI

```
config system interface
  edit <interface_name>
    set status down
  end
```

## RADIUS authentication for administrators

Remote Authentication and Dial-in User Service (RADIUS) servers provide authentication, authorization, and accounting functions. FortiGate units use the authentication and authorization functions of the RADIUS server. To use the RADIUS server for authentication, you must configure the server before configuring the FortiGate users or user groups that will need it.

If you have configured RADIUS support and a user is required to authenticate using a RADIUS server, the FortiGate unit sends the user's credentials to the RADIUS server for authentication. If the RADIUS server can authenticate the user, the user is successfully authenticated with the FortiGate unit. If the RADIUS server cannot authenticate the user, the FortiGate unit refuses the connection.

If you want to use a RADIUS server to authenticate administrators in your VDOM, you must configure the authentication before you create the administrator accounts. To do this you need to:

- configure the FortiGate unit to access the RADIUS server
- create the RADIUS user group
- configure an administrator to authenticate with a RADIUS server.

## Configuring LDAP authentication for administrators

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, printers, etc.

If you have configured LDAP support and an administrator is required to authenticate using an LDAP server, the FortiGate unit contacts the LDAP server for authentication. If the LDAP server cannot authenticate the administrator, the FortiGate unit refuses the connection.

If you want to use an LDAP server to authenticate administrators in your VDOM, you must configure the authentication before you create the administrator accounts. To do this you need to:

- configure an LDAP server
- create an LDAP user group
- configure an administrator to authenticate with an LDAP server.

To view the LDAP server list, go to *User & Device > Remote > LDAP*.

For more information, see [“LDAP Admin Access and Authorization”](#) on page 1432.

## TACACS+ authentication for administrators

Terminal Access Controller Access-Control System (TACACS+) is a remote authentication protocol that provides access control for routers, network access servers, and other network computing devices via one or more centralized servers.

If you have configured TACACS+ support and an administrator is required to authenticate using a TACACS+ server, the FortiGate unit contacts the TACACS+ server for authentication. If the TACACS+ server cannot authenticate the administrator, the connection is refused by the FortiGate unit.

If you want to use an TACACS+ server to authenticate administrators in your VDOM, you must configure the authentication before you create the administrator accounts. To do this you need to:

- configure the FortiGate unit to access the TACACS+ server
- create a TACACS+ user group
- configure an administrator to authenticate with a TACACS+ server.

### PKI certificate authentication for administrators

Public Key Infrastructure (PKI) authentication uses a certificate authentication library that takes a list of peers, peer groups, and user groups and returns authentication successful or denied notifications. Users only need a valid certificate for successful authentication; no username or password is necessary.

To use PKI authentication for an administrator, you must configure the authentication before you create the administrator accounts. To do this you need to:

- configure a PKI user
- create a PKI user group
- configure an administrator to authenticate with a PKI certificate.

## General Settings

Go to *System > Admin > Settings* to configure basic settings for administrative access, password policies and displaying additional options in the web-based manager.

### Administrative port settings

The Administrative Settings enable you to change the default port configurations for administrative connections to the FortiGate unit for added security. When connecting to the FortiGate unit when the port has changed, the port must be included, such as `https://<ip_address>:<port>`. For example, if you are connecting to the FortiGate unit using port 99, the url would be `https://192.168.1.99:99`.

If you make a change to the default port number for HTTP, HTTPS, Telnet, or SSH, ensure that the port number is unique.

### Password policies

Password policies, available by going to *System > Admin > Settings*, enable you to create a password policy that any administrator or user who updates their password, must follow. Using the available options you can define the required length of the password, what it must contain (numbers, upper and lower case, and so on) and an expiry time frame.

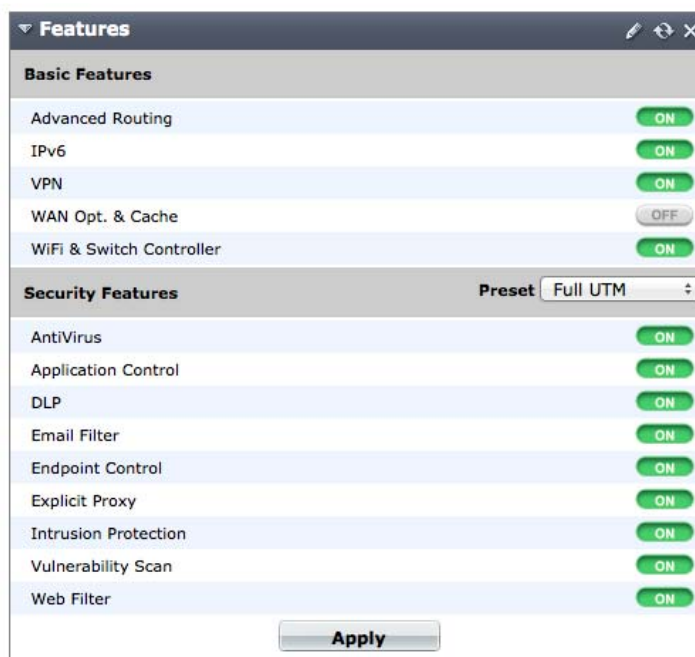

The FortiGate unit will warn of any password that is added and does not meet the criteria.

### Feature Select

Feature Select is used to disable features which are not required for network administration. Disabling features also removes all related configuration options from the web-based manager.

Feature Select can be managed using the *Features* widget on the *Status* page. They can also be found at *System > Config > Features*, where additional features are also available by selecting *Show More*.

**Figure 230:**The Features widget

If a feature, such as IPv6, has been configured before being removed from the web-based manager, this configuration will still exist as part of the network, even though it is no longer visible using the web-based manager.

## Configuration backups

Once you configure the FortiGate unit and it is working correctly, it is extremely important that you backup the configuration. In some cases, you may need to reset the FortiGate unit to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device will have to be recreated, unless a backup can be used to restore it.

It is also recommended that once *any* further changes are made that you backup the configuration immediately, to ensure you have the most current configuration available. Also, ensure you backup the configuration before upgrading the FortiGate unit's firmware. Should anything happen during the upgrade that changes the configuration, you can easily restore the saved configuration.

Always backup the configuration and store it on the management computer or off-site. You have the option to save the configuration file to various locations including the local PC, USB key, FTP and TFTP site. The latter two are configurable through the CLI only.

If you have VDOMs, you can back up the configuration of the entire FortiGate unit or only a specific VDOM. Note that if you are using FortiManager or FortiCloud, full backups are performed and the option to backup individual VDOMs will not appear.

### To back up the FortiGate configuration - web-based manager

1. Go to *System > Dashboard > Status*.
2. On the *System Information* widget, select *Backup* for the *System Configuration*.

3. Select to backup to your *Local PC* or to a *USB key*.  
The *USB Disk* option will be grayed out if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
4. If VDOMs are enabled, select to backup the entire FortiGate configuration (*Full Config*) or only a specific VDOM configuration (*VDOM Config*).
5. If backing up a VDOM configuration, select the VDOM name from the list.
6. Select *Encrypt configuration file*.  
Encryption must be enabled on the backup file to back up VPN certificates.
7. Enter a password and enter it again to confirm it. You will need this password to restore the file.
8. Select *Backup*.
9. The web browser will prompt you for a location to save the configuration file. The configuration file will have a .conf extension.

### To back up the FortiGate configuration - CLI

```
execute backup config management-station <comment>
```

... or ...

```
execute backup config usb <backup_filename> [<backup_password>]
```

... or for FTP, note that port number, username are optional depending on the FTP site...

```
execute backup config ftp <backup_filename> <ftp_server> [<port>]
[<user_name>] [<password>]
```

... or for TFTP ...

```
execute backup config tftp <backup_filename> <tftp_servers>
<password>
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config vdom
edit <vdom_name>
```

## Backup and restore a configuration file using SCP

You can use secure copy protocol (SCP) to download the configuration file from the FortiGate unit as an alternative method of backing up the configuration file or an individual VDOM configuration file. This is done by enabling SCP for an administrator account and enabling SSH on a port used by the SCP client application to connect to the FortiGate unit. SCP is enabled using the CLI commands:

```
config system global
set admin-scp enable
end
```

Use the same commands to backup a VDOM configuration by first entering the commands:

```
config global
set admin-scp enable
end
config vdom
edit <vdom_name>
```

## Enable SSH access on the interface

SCP uses the SSH protocol to provide secure file transfer. The interface you use for administration must allow SSH access.

### To enable SSH - web-based manager:

1. Go to *System > Network > Interface*.
2. Select the interface you use for administrative access and select *Edit*.
3. In the *Administrative Access* section, select *SSH*.
4. Select *OK*.

### To enable SSH - CLI:

```
config system interface
    edit <interface_name>
        set allowaccess ping https ssh
    end
```

When adding to, or removing a protocol, you must type the entire list again. For example, if you have an access list of HTTPS and SSH, and you want to add PING, typing:

```
set allowaccess ping
```

...only PING will be set. In this case, you must type...

```
set allowaccess https ssh ping
```

## Using the SCP client

The FortiGate unit downloads the configuration file as `sys_conf`. Use the following syntax to download the file:

### Linux

```
scp admin@<FortiGate_IP>:fgt-config <location>
```

### Windows

```
pscp admin@<FortiGate_IP>:fgt-config <location>
```

The following examples show how to download the configuration file from a FortiGate-100D, at IP address 172.20.120.171, using Linux and Windows SCP clients.

### Linux client example

To download the configuration file to a local directory called `~/config`, enter the following command:

```
scp admin@172.20.120.171:fgt-config ~/config
```

Enter the admin password when prompted.

### Windows client example

To download the configuration file to a local directory called `c:\config`, enter the following command in a Command Prompt window:

```
pscp admin@172.20.120.171:fgt-config c:\config
```

Enter the admin password when prompted.

## SCP public-private key authentication

SCP authenticates itself to the FortiGate unit in the same way as an administrator using SSH accesses the CLI. Instead of using a password, you can configure the SCP client and the FortiGate unit with a public-private key pair.

### To configure public-private key authentication

1. Create a public-private key pair using a key generator compatible with your SCP client.
2. Save the private key to the location on your computer where your SSH keys are stored.  
This step depends on your SCP client. The Secure Shell key generator automatically stores the private key.

3. Copy the public key to the FortiGate unit using the CLI commands:

```
config system admin
    edit admin
        set ssh-public-key1 "<key-type> <key-value>"
    end
```

<key-type> must be the ssh-dss for a DSA key or ssh-rsa for an RSA key. For the <key-value>, copy the public key data and paste it into the CLI command.

If you are copying the key data from Windows Notepad, copy one line at a time and ensure that you paste each line of key data at the end of the previously pasted data. As well:

- Do not copy the end-of-line characters that appear as small rectangles in Notepad.
- Do not copy the ---- BEGIN SSH2 PUBLIC KEY ---- or Comment: "[2048-bit dsa, ...]" lines.
- Do not copy the ---- END SSH2 PUBLIC KEY ---- line.

4. Type the closing quotation mark and press Enter.

Your SCP client can now authenticate to the FortiGate unit based on SSH keys rather than the administrator password.

## Restoring a configuration using SCP

To restore the configuration using SCP, use the commands:

```
scp <local_file> <admin_user>@<FGT_IP>:fgt_restore_config
```

To use this command/method of restoring the FortiGate configuration, you need to log in as the "admin" administrator.

## Restoring a configuration

Should you need to restore a configuration file, use the following steps:

### To restore the FortiGate configuration - web-based manager

1. Go to *System > Dashboard > Status*.
2. On the *System Information* widget, select *Restore* for the *System Configuration*.
3. Select to upload the configuration file to be restored from your *Local PC* or a *USB key*.  
The *USB Disk* option will be grayed out if no USB drive is inserted in the USB port. You can restore from the FortiManager using the CLI.
4. Enter the path and file name of the configuration file, or select *Browse* to locate the file.
5. Enter a password if required.
6. Select *Restore*.

### To back up the FortiGate configuration - CLI

```
execute restore config management-station normal 0
```

... or ...

```
execute restore config usb <filename> [<password>]
```

... or for FTP, note that port number, username are optional depending on the FTP site...

```
execute backup config ftp <backup_filename> <ftp_server> [<port>]  
[<user_name>] [<password>]
```

... or for TFTP ...

```
execute backup config tftp <backup_filename> <tftp_server> <password>
```

The FortiGate unit will load the configuration file and restart. Once the restart has completed, verify that the configuration has been restored.

## Configuration revisions

The *Revisions* options on the *System Information* widget enables you to manage multiple versions of configuration files. Revision control requires either a configured central management server, or FortiGate units with 512 MB or more of memory. The central management server can either be a FortiManager unit or the FortiCloud.

When revision control is enabled on your unit, and configurations have been backed up, a list of saved revisions of those backed-up configurations appears.

## Restore factory defaults

There may be a point where need to reset the FortiGate unit to its original defaults; for example, to begin with a fresh configuration. There are two options when restoring factory defaults. The first resets the entire device to the original out-of-the-box configuration:

### To reset the FortiGate unit to its factory default settings - web-based manager

1. Go to *System > Dashboard > Status*.
2. In the *System Information* widget, select *Restore* for the *System Configuration*.
3. Select *Restore Factory Defaults* at the top of the page.

### You can reset using the CLI by entering the command:

```
execute factoryreset
```

When prompted, type *y* to confirm the reset.

Alternatively, in the CLI you can reset the factory defaults but retain the interface and VDOM configuration.

Use the command:

```
execute factoryreset2
```

## Firmware

Fortinet periodically updates the FortiGate firmware to include new features and resolve important issues. After you have registered your FortiGate unit, you can download firmware updates from the support web site, <http://support.fortinet.com>.

The FortiGate unit includes a number of firmware installation options that enables you to test new firmware without disrupting the existing installation, and load it from different locations as required.

Before you install any new firmware, be sure to follow the steps below:

- review the [Release Notes](#) for a new firmware release.
- review the [Supported Upgrade Paths](#) document to make sure the upgrade from your current image to the desired new image is supported.
- backup the current configuration.
- download the new firmware image.
- test the patch release until you are satisfied that it applies to your configuration.

Installing a patch release without reviewing release notes or testing the firmware may result in changes to settings or unexpected issues.

Only FortiGate admin user and administrators whose access profiles contain system read and write privileges can change the FortiGate firmware.

## Downloading firmware

Firmware images for all FortiGate units is available on the Fortinet Customer Support website. You must register your FortiGate unit to access firmware images. Register the FortiGate unit by visiting <http://support.fortinet.com> and select Product Registration.

### To download firmware

1. Log into the site using your user name and password.
2. Go to *Firmware Images* > *FortiGate*.
3. Select the most recent FortiOS version.
4. Locate the firmware for your FortiGate unit, right-click the link and select the Download option for your browser.

## Testing new firmware before installing

FortiOS enables you to test a new firmware image by installing the firmware image from a system reboot and saving it to system memory. After completing this procedure, the FortiGate unit operates using the new firmware image with the current configuration. This new firmware image is not permanently installed. The next time the FortiGate unit restarts, it operates with the originally installed firmware image using the current configuration. If the new firmware image operates successfully, you can install it permanently using the procedure “[Upgrading the firmware - web-based manager](#)” on page 1449.

To use this procedure, you must connect to the CLI using the FortiGate console port and a RJ-45 to DB-9 or null modem cable. This procedure temporarily installs a new firmware image using your current configuration.

For this procedure you install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

### To test the new firmware image

1. Connect to the CLI using a RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the FortiGate unit can connect to the TFTP server using the `execute ping` command.

5. Enter the following command to restart the FortiGate unit:  
`execute reboot`
6. As the FortiGate unit reboots, press any key to interrupt the system startup. As the FortiGate unit starts, a series of system startup messages appears.  
When the following messages appears:  
Press any key to display configuration menu....
7. Immediately press any key to interrupt the system startup.

You have only 3 seconds to press any key. If you do not press a key soon enough, the FortiGate unit reboots and you must login and repeat the `execute reboot` command.

---

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.  
[F]: Format boot device.  
[B]: Boot with backup firmware and set as default  
[C]: Configuration and information  
[Q]: Quit menu and continue to boot with default  
firmware.  
[H]: Display this list of options.
```

Enter G, F, Q, or H:

8. Type G to get the new firmware image from the TFTP server.  
The following message appears:  
Enter TFTP server address [192.168.1.168]:
9. Type the address of the TFTP server and press Enter:  
The following message appears:  
Enter Local Address [192.168.1.188]:
10. Type an IP address of the FortiGate unit to connect to the TFTP server.  
The IP address must be on the same network as the TFTP server.

Make sure you do not enter the IP address of another device on this network.

---

The following message appears:

Enter File Name [image.out]:

11. Enter the firmware image file name and press Enter.

The TFTP server uploads the firmware image file to the FortiGate unit and the following appears.

Save as Default firmware/Backup firmware/Run image without saving:  
[D/B/R]

12. Type R.

The FortiGate image is installed to system memory and the FortiGate unit starts running the new firmware image, but with its current configuration.

You can test the new firmware image as required. When done testing, you can reboot the FortiGate unit, and the FortiGate unit will resume using the firmware that was running before you installed the test firmware.

## Upgrading the firmware - web-based manager

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date.

Always remember to back up your configuration before making any changes to the firmware.

### To upgrade the firmware

1. Log into the web-based manager as the admin administrative user.
2. Go to *System > Dashboard > Status*.
3. Under *System Information > Firmware Version*, select *Update*.
4. Type the path and filename of the firmware image file, or select *Browse* and locate the file.
5. Select *OK*.

The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, restarts, and displays the FortiGate login. This process takes a few minutes.

## Upgrading the firmware - CLI

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date. You can also use the CLI command `execute update-now` to update the antivirus and attack definitions. For more information, see the [FortiGate Administration Guide](#).

Before you begin, ensure you have a TFTP server running and accessible to the FortiGate unit.

Always remember to back up your configuration before making any changes to the firmware.

### To upgrade the firmware using the CLI

1. Make sure the TFTP server is running.
2. Copy the new firmware image file to the root directory of the TFTP server.
3. Log into the CLI.
4. Make sure the FortiGate unit can connect to the TFTP server.

You can use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

```
execute ping 192.168.1.168
```

5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:

```
execute restore image tftp <filename> <tftp_ipv4>
```

Where <name\_str> is the name of the firmware image file and <tftp\_ip4> is the IP address of the TFTP server. For example, if the firmware image file name is `image.out` and the IP address of the TFTP server is 192.168.1.168, enter:

```
execute restore image tftp image.out 192.168.1.168
```

The FortiGate unit responds with the message:

This operation will replace the current firmware version!

Do you want to continue? (y/n)

6. Type `y`.
7. The FortiGate unit uploads the firmware image file, upgrades to the new firmware version, and restarts. This process takes a few minutes.
8. Reconnect to the CLI.
9. Update antivirus and attack definitions, by entering:

```
execute update-now
```

## Installing firmware from a system reboot using the CLI

There is a possibility that the firmware upgrade does not load properly and the FortiGate unit will not boot, or continuously reboots. If this occurs, it is best to perform a fresh install of the firmware from a reboot using the CLI.

This procedure installs a firmware image and resets the FortiGate unit to default settings. You can use this procedure to upgrade to a new firmware version, revert to an older firmware version, or re-install the current firmware.

To use this procedure, you must connect to the CLI using the FortiGate console port and a RJ-45 to DB-9, or null modem cable. This procedure reverts the FortiGate unit to its factory default configuration.

For this procedure you install a TFTP server that you can connect to from the FortiGate internal interface. The TFTP server should be on the same subnet as the internal interface.

Before beginning this procedure, ensure you back up the FortiGate unit configuration.

If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Installing firmware replaces your current antivirus and attack definitions, along with the definitions included with the firmware release you are installing. After you install new firmware, make sure that antivirus and attack definitions are up to date.

### To install firmware from a system reboot

1. Connect to the CLI using the RJ-45 to DB-9 or null modem cable.
2. Make sure the TFTP server is running.
3. Copy the new firmware image file to the root directory of the TFTP server.
4. Make sure the internal interface is connected to the same network as the TFTP server.
5. To confirm the FortiGate unit can connect to the TFTP server, use the following command to ping the computer running the TFTP server. For example, if the IP address of the TFTP server is 192.168.1.168:

```
execute ping 192.168.1.168
```

6. Enter the following command to restart the FortiGate unit.

```
execute reboot
```

The FortiGate unit responds with the following message:

```
This operation will reboot the system!
```

```
Do you want to continue? (y/n)
```

7. Type `y`.

As the FortiGate unit starts, a series of system startup messages appears. When the following messages appears:

```
Press any key to display configuration menu.....
```

Immediately press any key to interrupt the system startup.

You have only 3 seconds to press any key. If you do not press a key soon enough, the FortiGate unit reboots and you must log in and repeat the `execute reboot` command.

---

If you successfully interrupt the startup process, the following messages appears:

```
[G]: Get firmware image from TFTP server.
```

```
[F]: Format boot device.
```

```
[B]: Boot with backup firmware and set as default
```

```
[C]: Configuration and information
```

```
[Q]: Quit menu and continue to boot with default  
firmware.
```

```
[H]: Display this list of options.
```

```
Enter G, F, Q, or H:
```

8. Type `G` to get to the new firmware image form the TFTP server.

The following message appears:

```
Enter TFTP server address [192.168.1.168]:
```

9. Type the address of the TFTP server and press Enter:

The following message appears:

```
Enter Local Address [192.168.1.188]:
```

10. Type an IP address the FortiGate unit can use to connect to the TFTP server. The IP address can be any IP address that is valid for the network the interface is connected to.

Make sure you do not enter the IP address of another device on this network.

---

The following message appears:

```
Enter File Name [image.out]:
```

11. Enter the firmware image filename and press Enter.

The TFTP server uploads the firmware image file to the FortiGate unit and a message similar to the following appears:

```
Save as Default firmware/Backup firmware/Run image without saving:  
[D/B/R]
```

12 Type D.

The FortiGate unit installs the new firmware image and restarts. The installation might take a few minutes to complete.

## Reverting to a previous firmware version - web-based manager

The following procedures revert the FortiGate unit to its factory default configuration and deletes any configuration settings.

If you are reverting to a previous FortiOS version, you might not be able to restore the previous configuration from the backup configuration file.

Always remember to back up your configuration before making any changes to the firmware.

### To revert to a previous firmware version

1. Copy the firmware image file to the management computer.
2. Log into the FortiGate web-based manager.
3. Go to *System > Dashboard > Status*.
4. Under *System Information > Firmware Version*, select *Update*.
5. Type the path and filename of the firmware image file, or select *Browse* and locate the file.
6. Select *OK*.

The FortiGate unit uploads the firmware image file, reverts to the old firmware version, resets the configuration, restarts, and displays the FortiGate login. This process takes a few minutes.

7. Log into the web-based manager.
8. Restore your configuration.

For information about restoring your configuration see [“Restoring a configuration” on page 1445](#).

## Reverting to a previous firmware version - CLI

This procedure reverts the FortiGate unit to its factory default configuration and deletes IPS custom signatures, web content lists, email filtering lists, and changes to replacement messages.

Before beginning this procedure, it is recommended that you:

- back up the FortiGate unit system configuration using the command `execute backup config`
- back up the IPS custom signatures using the command `execute backup ipsuserdefsig`
- back up web content and email filtering lists

To use the following procedure, you must have a TFTP server the FortiGate unit can connect to.

### To revert to a previous firmware version using the CLI

1. Make sure the TFTP server is running
2. Copy the firmware image file to the root directory of the TFTP server.
3. Log into the FortiGate CLI.

4. Make sure the FortiGate unit can connect to the TFTP server execute by using the `execute ping` command.
5. Enter the following command to copy the firmware image from the TFTP server to the FortiGate unit:  

```
execute restore image tftp <name_str> <tftp_ipv4>
```

Where `<name_str>` is the name of the firmware image file and `<tftp_ipv4>` is the IP address of the TFTP server. For example, if the firmware image file name is `imagev28.out` and the IP address of the TFTP server is 192.168.1.168, enter:

```
execute restore image tftp image28.out 192.168.1.168
```

The FortiGate unit responds with this message:

```
This operation will replace the current firmware version!  
Do you want to continue? (y/n)
```
6. Type `y`.  
The FortiGate unit uploads the firmware image file. After the file uploads, a message similar to the following appears:  

```
Get image from tftp server OK.  
Check image OK.  
This operation will downgrade the current firmware version!  
Do you want to continue? (y/n)
```
7. Type `y`.
8. The FortiGate unit reverts to the old firmware version, resets the configuration to factory defaults, and restarts. This process takes a few minutes.
9. Reconnect to the CLI.
10. To restore your previous configuration, if needed, use the command:  

```
execute restore config <name_str> <tftp_ip4>
```
11. Update antivirus and attack definitions using the command:  

```
execute update-now.
```

## Configuration Revision

The *Configuration Revisions* menu enables you to manage multiple versions of configuration files on models that have a 512 flash memory and higher. Revision control requires either a configured central management server or the local hard drive. The central management server can either be a FortiManager unit or FortiCloud.

If central management is not configured on your FortiGate unit, a message appears to tell you to do one of the following:

- enable central management (see [Central management](#))
- obtain a valid license.

When revision control is enabled on your FortiGate unit, and configurations backups have been made, a list of saved revisions of those backed-up configurations appears.

Configuration revisions are viewed in the *System Information* widget on the Dashboard.

## Backup and Restore from a USB key

Use a USB key to either backup a configuration file or restore a configuration file. You should always make sure a USB key is properly install before proceeding since the FortiGate unit must recognize that the key is installed in its USB port.

You can only save VPN certificates if you encrypt the file. Make sure the configuration encryption is enabled so you can save the VPN certificates with the configuration file. An encrypted file is ineffective if selected for the USB Auto-Install feature.

#### **To backup configuration using the CLI**

1. Log into the CLI.
2. Enter the following command to backup the configuration files:  
`exec backup config usb <filename>`
3. Enter the following command to check the configuration files are on the key:  
`exec usb-disk list`

#### **To restore configuration using the CLI**

1. Log into the CLI.
2. Enter the following command to restore the configuration files:  
`exec restore image usb <filename>`  
The FortiGate unit responds with the following message:  
This operation will replace the current firmware version!  
Do you want to continue? (y/n)
3. Type y.
- 4.

### **Backup and Restore an encrypted config file from a USB key**

You can save and boot an encrypted configuration file from a USB key. The configuration will only load when rebooting the FortiGate unit with the USB key inserted.

The administrator must back up the configuration to the USB key using the command:

```
execute backup config usb-mode <password>
```

administrator backup the configuration, to the USB key ("exec backup config usb-mode")

Insert the USB key into any FortiGate unit running the same image/patch release as the FortiGate unit that created the configuration file

The Administrator runs the CLI command below to reboot the FortiGate unit and load the configuration file from the USB key:

```
execute restore config usb-mode <password>)
```

The FortiGate unit saves the password into the flash memory. When system boots, the FortiGate unit loads the configurations from the USB key using the saved password in the flash. This configuration is read-only. That is, no configuration changes can be made while running with the configuration. The administrator is not permitted to make any configuration changes while configurations are loaded from USB (read-only)

If the USB key is removed while the FortiGate unit is running, the FortiGate unit deletes the password from the flash memory and reboots.

### **Controlled upgrade**

Using a controlled upgrade, you can upload a new version of the FortiOS firmware to a separate partition in the FortiGate memory for later upgrade. The FortiGate unit can also be configured so that when it is rebooted, it will automatically load the new firmware (CLI only). Using this option, you can stage a number of FortiGate units to do an upgrade simultaneously to all devices using FortiManager or script.

### To load the firmware for later installation - web-based manager

1. Go to *System > Dashboard > Status*.
2. Under *System Information > Firmware Version*, select *Update*.
3. Type the path and filename of the firmware image file, or select *Browse* and locate the file.
4. Deselect the *Boot the New Firmware* option
5. Select *OK*.

### To load the firmware for later installation - CLI

```
execute restore secondary-image {ftp | tftp | usb}
```

To set the FortiGate unit so that when it reboots, the new firmware is loaded, use the CLI command...

```
execute set-next-reboot {primary | secondary}
```

... where {primary | secondary} is the partition with the preloaded firmware.

### To trigger the upgrade using the web-based manager

1. Go to *System > Dashboard > Status*.
2. Under *System Information > Firmware Version*, select *Details*.
3. Select the check box for the new firmware version.  
The *Comments* column indicates which firmware version is the current active version.
4. Select *Upgrade* icon.

# Best practices

The FortiGate unit is installed, and traffic is moving. With your network sufficiently protected, you can now fine-tune the firewall for the best performance and efficiency. This chapter describes configuration options that can ensure your FortiGate unit is running at its best performance.

This section includes the topics on:

- [Hardware](#)
- [Shutting down](#)
- [Performance](#)
- [Firewall](#)
- [Intrusion protection](#)
- [Antivirus](#)
- [Web filtering](#)
- [Antispam](#)

## Hardware

### Environmental specifications

Keep the following environmental specifications in mind when installing and setting up your FortiGate unit.

- Operating temperature: 32 to 104°F (0 to 40°C) (temperatures may vary, depending on the FortiGate model)
- If you install the FortiGate unit in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient temperature. Therefore, make sure to install the equipment in an environment compatible with the manufacturer's maximum rated ambient temperature.
- Storage temperature: -13 to 158°F (-25 to 70°C) (temperatures may vary, depending on the FortiGate model)
- Humidity: 5 to 90% non-condensing
- Air flow - For rack installation, make sure that the amount of air flow required for safe operation of the equipment is not compromised.
- For free-standing installation, make sure that the appliance has at least 1.5 in. (3.75 cm) of clearance on each side to allow for adequate air flow and cooling.

This device complies with part FCC Class A, Part 15, UL/CUL, C Tick, CE and VCCI. Operation is subject to the following two conditions:

- This device may not cause harmful interference, and
- This device must accept any interference received, including interference that may cause undesired operation.

This equipment has been tested and found to comply with the limits for a Class B digital device, pursuant to part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference in a residential installation. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with

the instructions, may cause harmful interference to radio communications. However, there is no guarantee that interference will not occur in a particular installation. If this equipment does cause harmful interference to radio or television reception, which can be determined by turning the equipment off and on, the user is encouraged to try to correct the interference by one or more of the following measures:

- Reorient or relocate the receiving antenna.
- Increase the separation between the equipment and receiver.
- Connect the equipment into an outlet on a circuit different from that to which the receiver is connected.
- Consult the dealer or an experienced radio/TV technician for help.

The equipment compliance with FCC radiation exposure limit set forth for uncontrolled Environment.

Risk of Explosion if battery is replaced by an incorrect type. Dispose of used batteries according to the instructions.

To reduce the risk of fire, use only No. 26 AWG or larger UL Listed or CSA Certified Telecommunication Line Cord

---

## Grounding

- Ensure the FortiGate unit is connected and properly grounded to a lightning and surge protector. WAN or LAN connections that enter the premises from outside the building should be connected to an Ethernet CAT5 (10/100 Mb/s) surge protector.
- Shielded Twisted Pair (STP) Ethernet cables should be used whenever possible rather than Unshielded Twisted Pair (UTP).
- Do not connect or disconnect cables during lightning activity to avoid damage to the FortiGate unit or personal injury.

## Rack mount instructions

**Elevated Operating Ambient** - If installed in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient. Therefore, consideration should be given to installing the equipment in an environment compatible with the maximum ambient temperature (T<sub>ma</sub>) specified by the manufacturer.

**Reduced Air Flow** - Installation of the equipment in a rack should be such that the amount of air flow required for safe operation of the equipment is not compromised.

**Mechanical Loading** - Mounting of the equipment in the rack should be such that a hazardous condition is not achieved due to uneven mechanical loading.

**Circuit Overloading** - Consideration should be given to the connection of the equipment to the supply circuit and the effect that overloading of the circuits might have on overcurrent protection and supply wiring. Appropriate consideration of equipment nameplate ratings should be used when addressing this concern.

**Reliable Earthing** - Reliable earthing of rack-mounted equipment should be maintained.

Particular attention should be given to supply connections other than direct connections to the branch circuit (e.g. use of power strips).

## Shutting down

Always shut down the FortiGate operating system properly before turning off the power switch to avoid potential hardware problems.

### To power off the FortiGate unit - web-based manager

1. Go to *System > Status*.
2. In the *System Resources* widget, select *Shutdown*.

### To power off the FortiGate unit - CLI

```
execute shutdown
```

Once this has been done, you can safely turn off the power switch or disconnect the power cables from the power supply.

## Performance

- Disable any management features you do not need. If you don't need SSH or SNMP, disable them. SSH also provides another possibility for would-be hackers to infiltrate your FortiGate unit.
- Put the most used firewall rules to the top of the interface list.
- Log only necessary traffic. The writing of logs, especially if to an internal hard disk, slows down performance.
- Enable only the required application inspections.
- Keep alert systems to a minimum. If you send logs to a syslog server, you may not need SNMP or email alerts, making for redundant processing.
- Establish scheduled FortiGuard updates at a reasonable rate. Daily updates occurring every 4-5 hours are sufficient for most situations. In more heavy-traffic situations, schedule updates for the evening when more bandwidth can be available.
- Keep security profiles to a minimum. If you do not need a profile on a firewall rule, do not include it.
- Keep VDOMs to a minimum. On low-end FortiGate units, avoid using them if possible.
- Avoid traffic shaping if you need maximum performance. Traffic shaping, by definition, slows down traffic.

## Firewall

- Avoid using the *All* selection for the source and destination addresses. Use addresses or address groups.
- Avoid using *Any* for the services.
- Use logging on a policy only when necessary and be aware of the performance impact. For example, you may want to log all dropped connections but can choose to use this sparingly

by sampling traffic data rather than have it continually storing log information you may not use.

- Use the comment field to input management data, for example: who requested the rule, who authorized it, etc.
- Avoid FQDN addresses if possible, unless they are internal. It can cause a performance impact on DNS queries and security impact from DNS spoofing.
- If possible, avoid port ranges on services for security reasons.
- Use groups whenever possible.
- To ensure that all AV push updates occur, ensure you have an AV profile enabled in a security policy.

## Intrusion protection

- Create and use security profiles with specific signatures and anomalies you need per-interface and per-rule.
- Do not use predefined or generic profiles. While these profiles are convenient to supply immediate protection, you should create profiles to suit your network environment.
- If you do use the default profiles, reduce the IPS signatures/anomalies enabled in the profile to conserve processing time and memory.
- If you are going to enable anomalies, make sure you tune thresholds according to your environment.
- If you need protection, but not audit information, disable the logging option.
- Tune the IP-protocol parameter accordingly.

## Antivirus

- Enable only the protocols you need to scan. If you have antivirus scans occurring on the SMTP server, or use FortiMail, it is redundant to have scanning occur on the FortiGate unit as well.
- Reduce the maximum file size to be scanned. Viruses usually travel in small files of around 1 to 2 megabytes.
- Antivirus scanning within an HA cluster can impact performance.
- Enable grayware scanning on security profiles tied to Internet browsing.
- Do not quarantine files unless you regularly monitor and review them. This is otherwise a waste of space and impacts performance.
- Use file patterns to avoid scanning where it is not required.
- Enable heuristics from the CLI if high security is required using the command `config antivirus heuristic`.

## Web filtering

- Web filtering within an HA cluster impacts performance.
- Always review the DNS settings to ensure the servers are fast.
- Content blocking may cause performance overhead.
- Local URL filters are faster than FortiGuard web filters, because the filter list is local and the FortiGate unit does not need to go out to the Internet to get the information from a FortiGuard web server.

## Antispam

- If possible use, a FortiMail unit. The antispam engines are more robust.
- Use fast DNS servers.
- Use specific security profiles for the rule that will use antispam.
- DNS checks may cause false positive with HELO DNS lookup.
- Content analysis (banned words) may impose performance overhead.

## Security

- Use NTP to synchronize time on the FortiGate and the core network systems, such as email servers, web servers, and logging services.
- Enable log rules to match corporate policy. For example, log administration authentication events and access to systems from untrusted interfaces.
- Minimize adhoc changes to live systems, if possible, to minimize interruptions to the network. When not possible, create backup configurations and implement sound audit systems using FortiAnalyzer and FortiManager.
- If you only need to allow access to a system on a specific port, limit the access by creating the strictest rule possible.

# FortiGuard

The FortiGuard Distribution Network (FDN) of servers provides updates to antivirus, antispam and IPS definitions to your FortiGate unit. Worldwide coverage of FortiGuard services is provided by FortiGuard service points. FortiGuard Subscription Services provide comprehensive Unified Threat Management (UTM) security solutions to enable protection against content and network level threats.

The FortiGuard team can be found around the globe, monitoring virus, spyware and vulnerability activities. As vulnerabilities are found, signatures are created and pushed to the subscribed FortiGate units. The Global Threat Research Team enables Fortinet to deliver a combination of multi-layered security intelligence and provide true zero-day protection from new and emerging threats. The FortiGuard Network has data centers around the world located in secure, high availability locations that automatically deliver updates to the Fortinet security platforms to and protect the network with the most up-to-date information.

To ensure optimal response and updates, the FortiGate unit will contact a FortiGuard service point closest to the FortiGate installation, using the configured time zone information. FortiGuard services are continuously updated year-round, 24x7.

Every FortiGate unit includes a free 30-day FortiGuard trial license. FortiGuard license management is performed by Fortinet servers. The FortiGate unit automatically contacts a FortiGuard service point when enabling FortiGuard services. Contact Fortinet Technical Support to renew a FortiGuard license after the free trial.

This section includes the topics:

- [FortiGuard Services](#)
- [Antivirus and IPS](#)
- [Web filtering](#)
- [Email filtering](#)
- [Security tools](#)
- [Troubleshooting](#)

## FortiGuard Services

The FortiGuard services provide a number of services to monitor world-wide activity and provide the best possible security.

### Next Generation Firewall

The Next Generation Firewall (NGFW) offers integrated, high-performance protection against today's wide range of advanced threats targeting your applications, data, and users.

NGFW services include:

- ***Intrusion Prevention System (IPS)***- The FortiGuard Intrusion Prevention System (IPS) uses a customizable database of more than 4000 known threats to stop attacks that evade conventional firewall defenses. It also provides behavior-based heuristics, enabling the

system to recognize threats when no signature has yet been developed. It also provides more than 1000 application identity signatures for complete application control.

- **Application Control** - Application Control allows you to identify and control applications on networks and endpoints regardless of port, protocol, and IP address used. It gives you unmatched visibility and control over application traffic, even traffic from unknown applications and sources.

## Advanced Threat Protection

Advanced Threat Protect (ATP) provides protection against a variety of threats, including Advanced Targeted Attacks (ATA), also known as Advanced Persistent Threats (APT).

ATP services include:

- **Antivirus** - The FortiGuard Antivirus Service provides fully automated updates to ensure protection against the latest content level threats. It employs advanced virus, spyware, and heuristic detection engines to prevent both new and evolving threats from gaining access to your network and protects against vulnerabilities.
- **Web Filtering** - Web Filtering provides Web URL filtering to block access to harmful, inappropriate, and dangerous web sites that may contain phishing/pharming attacks, malware such as spyware, or objectionable content that can expose your organization to legal liability. Based on automatic research tools and targeted research analysis, real-time updates enable you to apply highly-granular policies that filter web access based on 78 web content categories, over 45 million rated web sites, and more than two billion web pages - all continuously updated.

## Other Services

FortiGuard provides a number of additional services, including:

- **Vulnerability Scanning** - FortiGuard Services provide comprehensive and continuous updates for vulnerabilities, remediation, patch scan, and configuration benchmarks.
- **Email Filtering** - The FortiGuard Antispam Service uses both a sender IP reputation database and a spam signature database, along with sophisticated spam filtering tools on Fortinet appliances and agents, to detect and block a wide range of spam messages. Updates to the IP reputation and spam signature databases are provided continuously via the FDN.
- **Messaging Services** - Messaging Services allow a secure email server to be automatically enabled on your FortiGate unit to send alert email or send email authentication tokens. With the SMS gateway, you can enter phone numbers where the FortiGate unit will send the SMS messages.  
Note that depending on your carrier, there may be a slight time delay on receiving messages.
- **DNS and DDNS** - The FortiGuard DNS and DDNS services provide an efficient method of DNS lookups once subscribed to the FortiGuard network. This is the default option. The FortiGate unit connects automatically to the FortiGuard DNS server. If you do not register, you need to configure an alternate DNS server.

Configure the DDNS server settings using the CLI commands:

```
config system fortiguard
    set ddns-server-ip
    set ddns-server-port
end
```

## Support Contract and FortiGuard Subscription Services

The *Support Contract* and *FortiGuard Subscription Services* sections are displayed in abbreviated form within the *License Information* widget. A detailed version is available by going to *System > Config > FortiGuard*.

The Support Contract area displays the availability or status of your FortiGate unit's support contract. The status displays can be either *Unreachable*, *Not Registered*, or *Valid Contract*.

The FortiGuard Subscription Services area displays detailed information about your FortiGate unit's support contract and FortiGuard subscription services. On this page, you can also manually update the antivirus and IPS engines.

The status icons for each section indicates the state of the subscription service. The icon corresponds to the availability description.

- **Gray (Unreachable)** – the FortiGate unit is not able to connect to service.
- **Orange (Not Registered)** – the FortiGate unit can connect, but not subscribed.
- **Yellow (Expired)** – the FortiGate unit had a valid license that has expired.
- **Green (Valid license)** – the FortiGate unit can connect to FDN and has a registered support contract. If the Status icon is green, the expiry date also appears.

## FortiCloud

FortiCloud is a hosted security management and log retention service for FortiGate products. It gives you a centralized reporting, traffic analysis, configuration and log retention without the need for additional hardware and software.

A subscription to FortiCloud also includes Cloud Sandbox, a service in which suspicious files can be inspected in isolation from your network.

For more information about FortiCloud, see [“FortiCloud” on page 1474](#).

## Antivirus and IPS

The FortiGuard network is an always updating service, including grayware and signatures for application control. There are two methods of updating the virus and IPS signatures on your FortiGate unit: manually or through push updates.

### Detection during update

During an update, the FortiGate unit will continue to detect to scan network traffic. Sessions occurring right before an update will be scanned using the current signatures. Sessions that occur during the update, when the signature database is reloading, will be on hold until the signatures load, at which point the new signatures are used to scan these sessions. Sessions occurring right after the update will also use the new signatures.

## Antivirus and IPS Options

Go to *System > Config > FortiGuard*, and expand the *AV and IPS Options* section to configure the antivirus and IPS options for connecting and downloading definition files.

<b>Use override server address</b>	Select to configure an override server if you cannot connect to the FDN or if your organization provides updates using their own FortiGuard server.
<b>Allow Push Update</b>	Select to allow updates sent automatically to your FortiGate unit when they are available
<b>Allow Push Update status icon</b>	<p>The status of the FortiGate unit for receiving push updates:</p> <ul style="list-style-type: none"><li>• <b>Gray (Unreachable)</b> - the FortiGate unit is not able to connect to push update service</li><li>• <b>Yellow (Not Available)</b> - the push update service is not available with your current support license</li><li>• <b>Green (Available)</b> - the push update service is allowed.</li></ul>
<b>Use override push IP and Port</b>	<p>Available only if both <i>Use override server address</i> and <i>Allow Push Update</i> are enabled.</p> <p>Enter the IP address and port of the NAT device in front of your FortiGate unit. FDS will connect to this device when attempting to reach the FortiGate unit.</p> <p>The NAT device must be configured to forward the FDS traffic to the FortiGate unit on UDP port 9443.</p>
<b>Schedule Updates</b>	<p>Select this check box to enable updates to be sent to your FortiGate unit at a specific time. For example, to minimize traffic lag times, you can schedule the update to occur on weekends or after work hours.</p> <p>Note that a schedule of once a week means any urgent updates will not be pushed until the scheduled time. However, if there is an urgent update required, select the <i>Update Now</i> button.</p>
<b>Update Now</b>	Select to manually initiate an FDN update.
<b>Submit attack characteristics... (recommended)</b>	Select to help Fortinet maintain and improve IPS signatures. The information sent to the FortiGuard servers when an attack occurs and can be used to keep the database current as variants of attacks evolve.

## Manual updates

To manually update the signature definitions file, you need to first go to the Support web site at <https://support.fortinet.com>. Once logged in, select FortiGuard Service Updates from the Download area of the web page. The browser will present you the most current antivirus and IPS signature definitions which you can download.

Once downloaded to your computer, log into the FortiGate unit to load the definition file.

### To load the definition file onto the FortiGate unit

1. Go to *System > Config > FortiGuard*.
2. Select the *Update* link for either *AV Definitions* or *IPS Definitions*.
3. Locate the downloaded file and select *OK*.

The upload may take a few minutes to complete.

## Automatic updates

The FortiGate unit can be configured to request updates from the FortiGuard Distribution Network. You can configure this to be on a scheduled basis, or with push notifications.

### Scheduling updates

Scheduling updates ensures that the virus and IPS definitions are downloaded to your FortiGate unit on a regular basis, ensuring that you do not forget to check for the definition files yourself. As well, by scheduling updates during off-peak hours, such as evenings or weekends, when network usage is minimal, ensures that the network activity will not suffer from the added traffic of downloading the definition files.

If you require the most up-to-date definitions as viruses and intrusions are found in the wild, the FortiGuard Distribution Network can push updates to the FortiGate units as they are developed. This ensures that your network will be protected from any breakouts of a virus within the shortest amount of time, minimizing any damaging effect that can occur. Push updates require that you have registered your FortiGate unit.

Once push updates are enabled, the next time new antivirus or IPS attack definitions are released, the FDN notifies all the FortiGate unit that a new update is available. Within 60 seconds of receiving a push notification, the unit automatically requests the update from the FortiGuard servers.

### To enable scheduled updates - web-based manager

1. Go to *System > Config > FortiGuard*.
2. Click the Expand Arrow for *AV and IPS Options*.
3. Select the *Scheduled Update* check box.
4. Select the frequency of the updates and when within that frequency.
5. Select *Apply*.

### To enable scheduled updates - CLI

```
config system autoupdate schedule
    set status enable
    set frequency {every | daily | weekly}
    set time <hh:mm>
    set day <day_of_week>
end
```

## Push updates

Push updates enable you to get immediate updates when new virus or intrusions have been discovered and new signatures are created. This ensures that when the latest signature is available it will be sent to the FortiGate.

When a push notification occurs, the FortiGuard server sends a notice to the FortiGate unit that there is a new signature definition file available. The FortiGate unit then initiates a download of the definition file, similar to the scheduled update.

To ensure maximum security for your network, you should have a scheduled update as well as enable the push update, in case an urgent signature is created, and your cycle of the updates only occurs weekly.

#### **To enable push updates - web-based manager**

1. Got to *System > Config > FortiGuard*.
2. Click the Expand Arrow for *AV and IPS Options*.
3. Select *Allow Push Update*.
4. Select *Apply*.

#### **To enable push updates - CLI**

```
config system autoupdate push-update
    set status enable
end
```

### **Push IP override**

If the FortiGate unit is behind another NAT device (or another FortiGate unit), to ensure it receives the push update notifications, you need to use an override IP address for the notifications. To do this, you create a virtual IP to map to the external port of the NAT device.

Generally speaking, if there are two FortiGate devices as in the diagram below, the following steps need to be completed on the FortiGate NAT device to ensure the FortiGate unit on the internal network receives the updates:

- Add a port forwarding virtual IP to the FortiGate NAT device that connects to the Internet by going to *Firewall Objects > Virtual IP*.
- Add a security policy to the FortiGate NAT device that connects to the Internet that includes the port forwarding virtual IP.
- Configure the FortiGate unit on the internal network with an override push IP and port.

On the FortiGate internal device, the virtual IP is entered as the *Use push override IP* address.

**Figure 231:**Using a virtual IP for a FortiGate unit behind a NAT device

**To enable push update override- web-based manager**

1. Got to *System > Config > FortiGuard*.
2. Click the Expand Arrow for *AV and IPS Options*.
3. Select *Allow Push Update*.
4. Select *Use push override IP*.
5. Enter the virtual IP address configured on the NAT device.
6. Select *Apply*.

**To enable push updates - CLI**

```
config system autoupdate push-update
  set status enable
  set override enable
  set address <vip_address>
end
```

## Web filtering

The multiple FortiGuard data centers around the world hold the entire categorized URL database and receive rating requests from customer-owned FortiGate units, typically triggered by browser-based URL requests. When these rating requests are responded to with the categories stored for specific URLs, the requesting FortiGate unit will then use its own local profile configuration to determine what action to take, for example blocking, monitoring, or permitting the URL request.

Rating responses can also be cached locally on the FortiGate unit, providing a quicker response time while easing load on the FortiGuard servers and aiding in a quicker response time for less common URL requests. This is a very effective method for common sites such as search

engines and other frequently visited sites. Other sites that are less frequently visited can also be cached locally for a determined amount of time.

By default, the web filtering cache is enabled. The cache includes a time-to-live value, which is the amount of time a URL will stay in the cache before expiring. You can change this value to shorten or extend the time between 300 and 86400 seconds. For a site such as Google, the frequency of its access can keep it in the cache, while other sites can remain in the cache up to 24 hours, or less depending on the configuration.

## Web Filtering and Email Filtering Options

Go to *System > Config > FortiGuard*, and expand arrow to view *Web Filtering and Email Filtering Options* for setting the size of the caches and ports used.

<b>Web Filter cache TTL</b>	Set the Time To Live value. This is the number of seconds the FortiGate unit will store a blocked IP or URL locally, saving time and network access traffic, checking the FortiGuard server. Once the TTL has expired, the FortiGate unit will contact an FDN server to verify a web address. The TTL must be between 300 and 86400 seconds.
<b>Antispam cache TTL</b>	Set the Time To Live value. This is the number of seconds the FortiGate unit will store a blocked IP or URL locally, saving time and network access traffic, checking the FortiGuard server. Once the TTL has expired, the FortiGate unit will contact an FDN server to verify a web address. The TTL must be between 300 and 86400 seconds.
<b>Port Section</b>	Select the port assignments for contacting the FortiGuard servers. Select the <i>Test Availability</i> button to verify the connection using the selected port.
<b>To have a URL's category rating re-evaluated, please click here</b>	Select to re-evaluate a URL's category rating on the FortiGuard Web Filter service.

## URL verification

If you discover a URL - yours or one you require access to has been incorrectly flagged as an inappropriate site - you can ask the FortiGuard team to re-evaluate the site. To do this, go to *System > Config > FortiGuard*, select the blue arrow for *Web Filtering and Email Filtering Options* and select the link for re-evaluation.

### To modify the web filter cache size - web-based manager

1. Got to *System > Config > FortiGuard*.
2. Click the Expand Arrow for *Web Filtering and Email Filtering Options*.
3. Enter the TTL value for the *Web filter cache*.
4. Select *Apply*.

### To modify the web filter cache size - CLI

```
config system fortiguard
    set webfilter-cache-ttl <integer>
end
```

Further web filtering options can be configured to block specific URLs, and allow others through. These configurations are available through the *Security Profiles > Web Filter* menu. For more information, see [Security](#) chapter of The Handbook.

## Email filtering

The FortiGuard data centers monitor and update email databases of known spam sources. With FortiGuard Antispam enabled, the FortiGate unit verifies incoming email sender address and IPs against the database, and take the necessary action as defined within the antivirus profiles.

Spam source IP addresses can also be cached locally on the FortiGate unit, providing a quicker response time, while easing load on the FortiGuard servers, aiding in a quicker response time for less common email address requests.

By default, the antispam cache is enabled. The cache includes a time-to-live value, which is the amount of time an email address will stay in the cache before expiring. You can change this value to shorten or extend the time between 300 and 86400 seconds.

### To modify the antispam filter cache size - web-based manager

1. Got to *System > Config > FortiGuard*.
2. Click the Expand Arrow for *Web Filtering and Email Filtering Options*.
3. Enter the TTL value for the *antispam cache*.
4. Select *Apply*.

### To modify the web filter cache size - CLI

```
config system fortiguard
    set antispam-cache-ttl <integer>
end
```

Further antispam filtering options can be configured to block, allow or quarantine, specific email addresses. These configurations are available through the *Security Profiles > Antispam* menu. For more information, see [Security Profiles](#) chapter of The Handbook.

## Security tools

The FortiGuard online center provides a number of online security tools that enable you to verify or check ratings of web sites, email addresses as well as check file for viruses. These features are available at <http://www.fortiguard.com>.

### URL lookup

By entering a web site address, you can see if it has been rated and what category and classification it is filed as. If you find your web site or a site you commonly go to has been wrongly categorized, you can use this page to request that the site be re-evaluated.

<http://www.fortiguard.com/webfiltering/webfiltering.html>

### IP and signature lookup

The IP and signature lookup enables you to check whether an IP address is blacklisted in the FortiGuard IP reputation database or whether a URL or email address is in the signature database.

<http://www.fortiguard.com/antispam/antispam.html>

## Online virus scanner

If you discover a suspicious file on your machine, or suspect that a program you downloaded from the Internet might be malicious you can scan it using the FortiGuard online scanner. The questionable file can be uploaded from your computer to a dedicated server where it will be scanned using FortiClient Antivirus. Only one file of up to 1 MB can be checked at any one time. All files will be forwarded to our research labs for analysis.

[http://www.fortiguard.com/antivirus/virus\\_scanner.html](http://www.fortiguard.com/antivirus/virus_scanner.html)

## Malware removal tools

Tools have been developed by FortiGuard Labs to disable and remove the specific malware and related variants. Some tools have been developed to remove specific malware, often tough to remove. A universal cleaning tool, FortiCleanup, is also available for download.

The FortiCleanup is a tool developed to identify and cleanse systems of malicious rootkit files and their associated malware. Rootkits consist of code installed on a system with kernel level privileges, often used to hide malicious files, keylog and thwart detection / security techniques. The aim of this tool is to reduce the effectiveness of such malware by finding and eliminating rootkits. The tool offers a quick memory scan as well as a full system scan. FortiCleanup will not only remove malicious files, but also can cleanse registry entries, kernel module patches, and other tricks commonly used by rootkits - such as SSDT hooks and process enumeration hiding.

A license to use these applications is provided free of charge, courtesy of Fortinet.

[http://www.fortiguard.com/antivirus/malware\\_removal.html](http://www.fortiguard.com/antivirus/malware_removal.html)

## FortiSandbox

A FortiSandbox unit can be used for automated sample tracking, or sandboxing, for files from a FortiGate unit. This allows suspicious files to be sent to be inspected without risking network security. If the file exhibits risky behavior, or is found to contain a virus, a new virus signature is created and added to the FortiGuard antivirus signature database.

Cloud Sandbox can also be used for sandboxing if you have an active FortiCloud subscription. For more information, see “FortiCloud” on page 1474.

## Troubleshooting

If you are not getting FortiGuard web filtering or antispam services, there are a few things to verify communication to the FortiGuard Distribution Network (FDN) is working. Before any troubleshooting, ensure that the FortiGate unit has been registered and you or your company, has subscribed to the FortiGuard services.

## Web-based manager verification

The simplest method to check that the FortiGate unit is communicating with the FDN, is to check the *License Information* dashboard widget. Any subscribed services should have a green check mark beside them indicating that connections are successful. Any other icon indicates a problem with the connection, or you are not subscribed to the FortiGuard services.

**Figure 232:**License Information widget showing FortiGuard availability

License Information		
<b>Support Contract</b>

## CLI verification

You can also use the CLI to see what FortiGuard servers are available to your FortiGate unit. Use the following CLI command to ping the FDN for a connection:

```
ping guard.fortinet.net
```

You can also use diagnose command to find out what FortiGuard servers are available:

```
diagnose debug rating
```

From this command, you will see output similar to the following:

```
Locale      : english
License     : Contract
Expiration  : Sun Jul 24 20:00:00 2011
Hostname    : service.fortiguard.net

--- Server List (Tue Nov  2 11:12:28 2010) ---

IP Weight    RTT Flags  TZ      Packets  Curr Lost Total Lost
69.20.236.180 0      10      -5      77200    0      42
69.20.236.179 0      12      -5      52514    0      34
66.117.56.42  0      32      -5      34390    0      62
80.85.69.38  50     164     0      34430    0     11763
208.91.112.194 81     223 D      -8      42530    0     8129
216.156.209.26 286    241 DI    -8      55602    0    21555
```

An extensive list of servers are available. Should you see a list of three to five available servers, the FortiGuard servers are responding to DNS replies to service.FortiGuard.net, but the INIT requests are not reaching FDS services on the servers.

The rating flags indicate the server status:

<b>D</b>	Indicates the server was found via the DNS lookup of the hostname. If the hostname returns more than one IP address, all of them will be flagged with 'D' and will be used first for INIT requests before falling back to the other servers.
<b>I</b>	Indicates the server to which the last INIT request was sent
<b>F</b>	The server has not responded to requests and is considered to have failed.
<b>T</b>	The server is currently being timed.

The server list is sorted first by weight and then the server with the smallest RTT is put at the top of the list, regardless of weight. When a packet is lost, it will be resent to the next server in the list.

The weight for each server increases with failed packets and decreases with successful packets. To lower the possibility of using a faraway server, the weight is not allowed to dip below a base weight, which is calculated as the difference in hours between the FortiGate unit and the server multiplied by 10. The further away the server is, the higher its base weight and the lower in the list it will appear.

## Port assignment

FortiGate units contact the FortiGuard Distribution Network (FDN) for the latest list of FDN servers by sending UDP packets with typical source ports of 1027 or 1031, and destination ports of 53 or 8888. The FDN reply packets have a destination port of 1027 or 1031.

If your ISP blocks UDP packets in this port range, the FortiGate unit cannot receive the FDN reply packets. As a result, the FortiGate unit will not receive the complete FDN server list.

If your ISP blocks the lower range of UDP ports (around 1024), you can configure your FortiGate unit to use higher-numbered ports, using the CLI command...

```
config system global
    set ip-src-port-range <start port>-<end port>
end
```

...where the <start port> and <end port> are numbers ranging of 1024 to 25000.

For example, you could configure the FortiGate unit to not use ports lower than 2048 or ports higher than the following range:

```
config system global
    set ip-src-port-range 2048-20000
end
```

Trial and error may be required to select the best source port range. You can also contact your ISP to determine the best range to use. Push updates might be unavailable if:

- there is a NAT device installed between the unit and the FDN
- your unit connects to the Internet using a proxy server.

# FortiCloud

FortiCloud is a hosted security management and log retention service for FortiGate products. It gives you a centralized reporting, traffic analysis, configuration and log retention without the need for additional hardware and software.

## FortiCloud Features

FortiCloud offers a wide range of features:

### **Simplified central management for your FortiGate network**

FortiCloud provides a central web-based management console to manage individual or aggregated FortiGate and FortiWifi devices. Adding a device to the FortiCloud management subscription is straightforward and provides detailed traffic and application visibility across the whole network.

### **Hosted log retention with large default storage allocated**

Log retention is an integral part of any security and compliance program but administering a separate storage system is burdensome. FortiCloud takes care of this automatically and stores the valuable log information in the cloud. Each device is allowed up to 200Gb of log retention storage. Different types of logs can be stored including Traffic, System Events, Web, Applications and Security Events.

### **Monitoring and alerting in real time**

Network availability is critical to a good end-user experience. FortiCloud enables you to monitor your FortiGate network in real time with different alerting mechanisms to pinpoint potential issues. Alerting mechanisms can be delivered via email.

### **Customized or pre-configured reporting and analysis tools**

Reporting and analysis are your eyes and ears into your network's health and security. Pre-configured reports are available, as well as custom reports that can be tailored to your specific reporting and compliance requirements. For example, you may want to look closely at application usage or web site violations. The reports can be emailed as PDFs and can cover different time periods.

### **Maintain important configuration information uniformly**

The correct configuration of the devices within your network is essential to maintaining an optimum performance and security posture. In addition, maintaining the correct firmware (operating system) level allows you to take advantage of the latest features.

### **Service security**

All communication (including log information) between the devices and the clouds is encrypted. Redundant data centers are always used to give the service high availability. Operational

security measures have been put in place to make sure your data is secure — only you can view or retrieve it.

## Registration and Activation

There are five key activation steps. The procedure for each step may vary depending on your model and your FortiOS firmware version, and whether your device (FortiGate or FortiWifi) is brand new.

The steps are:

1. Registering with Support (New devices only)
2. Activating your FortiCloud account
3. Enabling logging to FortiCloud
4. Logging into the FortiCloud portal
5. Upgrading to a 200Gb subscription (Recommended)

### Registering with Support

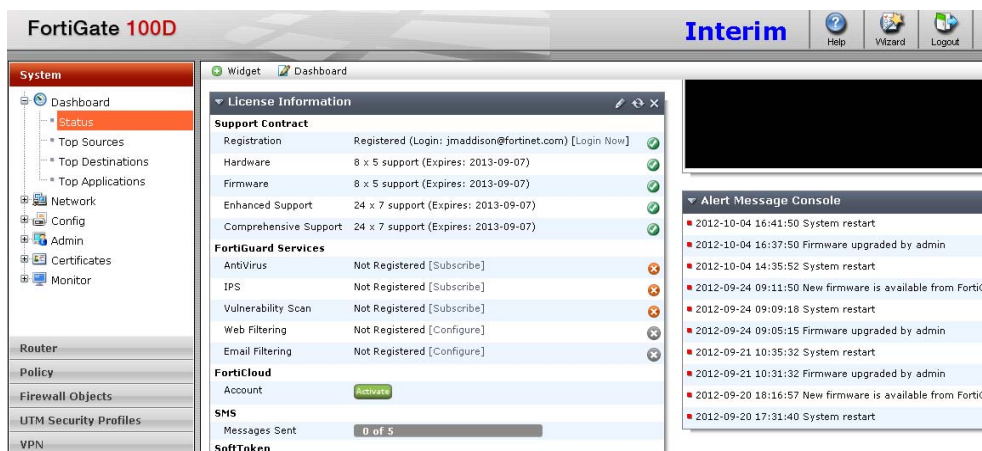

Registration is very important for new devices, as it allows interaction with the Fortinet back-end systems, such as support. This registration will also allow other services, such as support and data space expansion contracts, to be used with your FortiCloud account.

### Registering and Activating your FortiCloud account

FortiCloud accounts can be registered manually through the FortiCloud website, <https://www.forticloud.com>, but you can easily register and activate your account directly within your FortiGate unit. Your registration process will vary somewhat, depending on which firmware version and device you have.

#### FortiGate 300 and below, all FortiWifi units

1. On your device's dashboard, in the License Information widget, select the green *Activate* button in the FortiCloud section.

2. A dialogue asking you to register your FortiCloud account will appear. Enter your information, view and accept the Terms and Conditions and select *Create Account*.

3. A second dialogue window will appear, asking you to enter your information to confirm your account. This will send a confirmation email to your registered email. The dashboard widget will update to show that confirmation is required.

4. Open your email, and follow the confirmation link contained in it.

A FortiCloud page will open, stating that your account has been confirmed. The Activation Pending message on the dashboard will change to state the type of account you have ('1Gb Free' or '200Gb Subscription'), and will now provide a link to the FortiCloud portal.

## FortiGate 600 to 800

For 600 through 800, FortiCloud registration must be done through the FortiGate CLI Console. Devices beyond the FortiGate 800 do not support the FortiCloud service.

## Enabling logging to FortiCloud

In order to enable remote logging to the FortiCloud Service, you must first configure the FortiGate's log uploading settings. You must also enable logging in each policy that covers traffic that you want to be logged.

## FortiOS 5.0

FortiOS 5.0 will automatically start logging Traffic and Event logs to FortiCloud upon activation. Logging can be disabled or configured through the FortiGate interface or CLI Console.

## Configuring policies 5.0

After enabling logging functionality, you will need to select which policies will be logged.

1. Open the Policy list.
2. Choose the policy you would like to log, and select *Edit*.
3. Check the box next to *Log all sessions*.
4. Select *OK*.

## Logging into the FortiCloud portal

Once logging has been configured and you have registered your account, you can log into the FortiCloud portal and begin viewing your logging results. There are two methods to reach the FortiCloud portal:

- If you have direct networked access to the FortiGate unit, you can simply open your Dashboard and check the License Information widget. Next to the current FortiCloud connection status will be a link to reach the FortiCloud Portal.
- If you do not currently have access to the FortiGate's interface, you can visit the FortiCloud website (<https://forticloud.com>) and log in remotely, using your email and password. It will ask you to confirm the FortiCloud account you are connecting to and then you will be granted access. Connected devices can be remotely configured using the Scripts page in the Management Tab, useful if an administrator may be away from the unit for a long period of time.

## Upgrading to a 200Gb subscription

Upgrading your subscription is simple but must be done through the FortiGate unit, as the storage contract is allocated based on devices rather than user accounts.

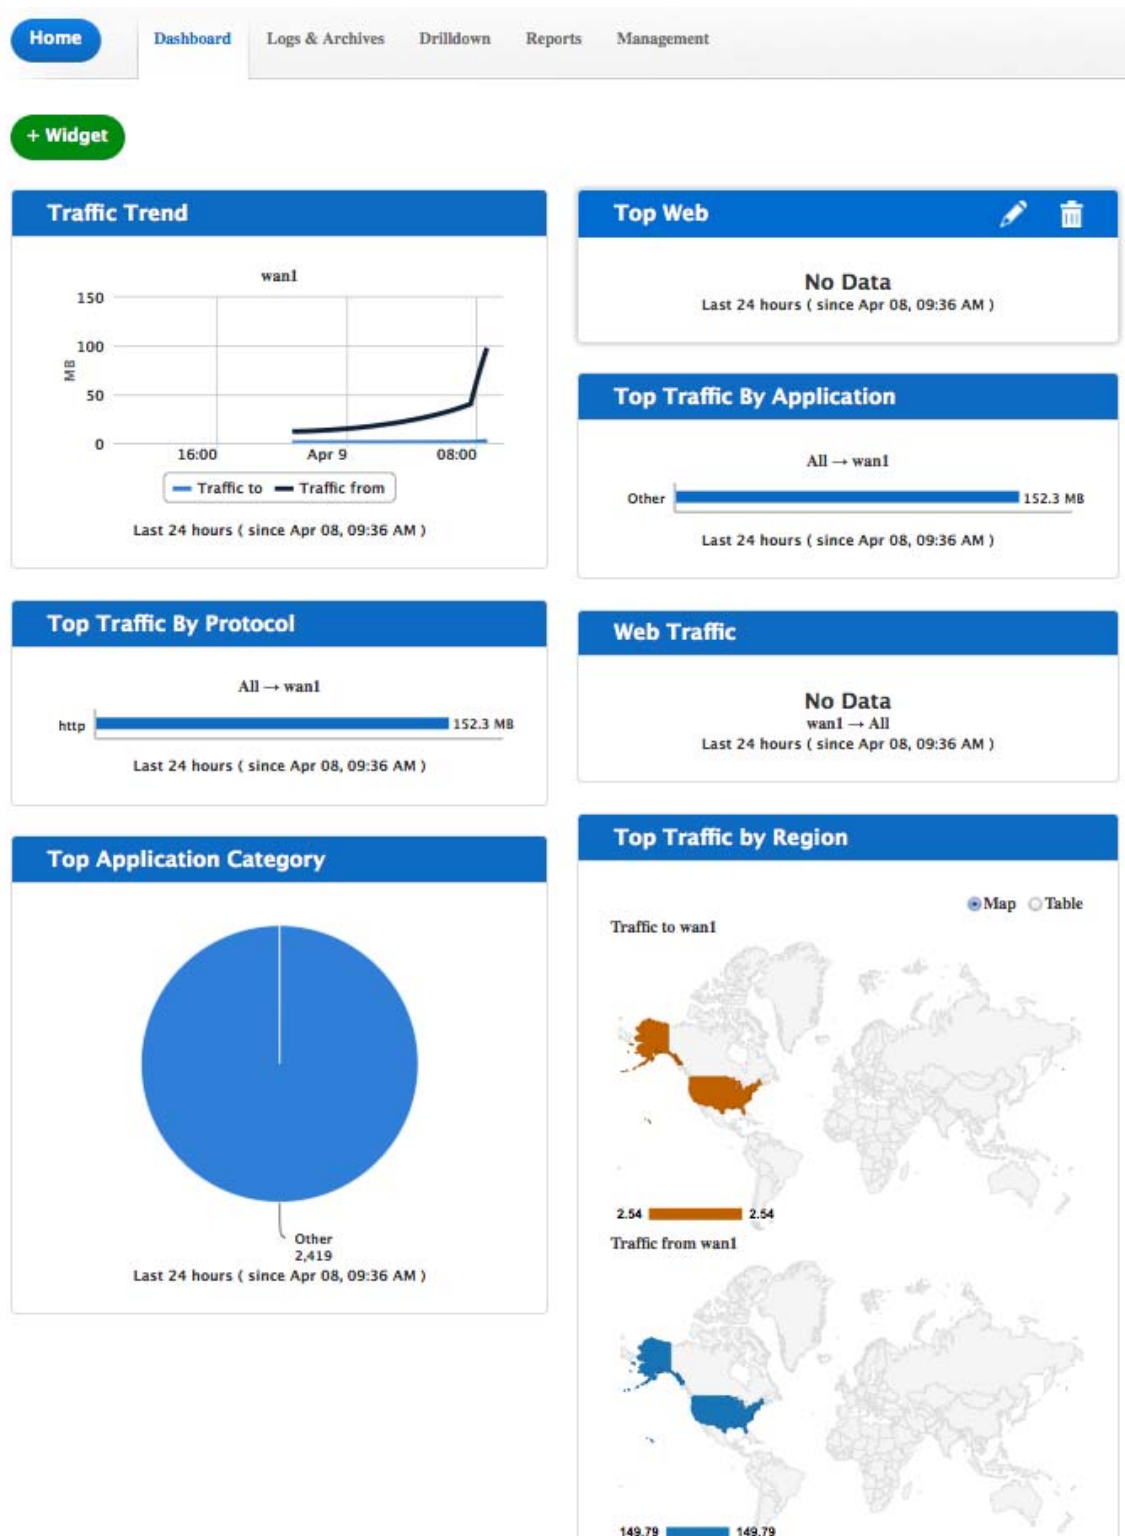

1. Open the FortiGate Dashboard.
2. In the License Information widget, select *Upgrade* next to 'Type' in the FortiCloud section.
3. A new window will open, showing the Fortinet Support portal. Follow the on-screen instructions to register your contract.
4. Wait approximately 10 minutes for the contract to be applied and then visit your Dashboard.

In the License Information widget, Type will have changed from 'Free' to 'Subscribed'. Your maximum listed storage will also have updated.

## The FortiCloud Portal

There are five main tabs in the FortiCloud portal, which allow you to access different features and information. The FortiCloud Settings, Help, and Logout buttons appear in the upper right.

- Dashboards
- Logs & Archives
- Drilldown
- Reports
- Management
- AV Submissions (this tab only appears if sandboxing has occurred, see "[Cloud Sandboxing](#)" on page 1479)

**Figure 234:**The FortiCloud Portal

## Using FortiCloud

Below is a list of possible tasks that show you how to make the best of the features that FortiCloud has to offer.

**Tasks:**

- Adding a new dashboard with custom charts
- Filtering logs to find specific information
- Downloading logs
- Using drilldown charts to find specific information
- Viewing and printing existing reports
- Generating scheduled and immediate reports
- Creating and configuring a new report with your logo
- Checking the status of your registration contract
- Adding a new user account to a FortiCloud account

For further information about using FortiCloud, please see the [FortiCloud Getting Started Guide](#).

## Cloud Sandboxing

FortiCloud can be used for automated sample tracking, or sandboxing, for files from a FortiGate unit. This allows suspicious files to be sent to be inspected without risking network security. If the file exhibits risky behavior, or is found to contain a virus, a new virus signature is created and added to the FortiGuard antivirus signature database. This feature was formerly known as FortiGuard Analytics.

Cloud sandboxing is configured by going to *System > Config > FortiSandbox*. After enabling FortiSandbox, select *Cloud Sandbox (FortiCloud)*.

Sandboxing results will be shown in a new tab called *AV Submissions* in the FortiCloud portal. This tab will only appear after a file has been sent for sandboxing.

# Interfaces

Interfaces, both physical and virtual, enable traffic to flow to and from the internal network, and the Internet and between internal networks. The FortiGate unit has a number of options for setting up interfaces and groupings of subnetworks that can scale to a company's growing requirements.

This chapter includes:

- [Physical](#)
- [Interface settings](#)
- [Software switch](#)
- [Virtual Switch](#)
- [Loopback interfaces](#)
- [Redundant interfaces](#)
- [One-armed sniffer](#)
- [Aggregate Interfaces](#)
- [DHCP addressing mode on an interface](#)
- [Administrative access](#)
- [Wireless](#)
- [Interface MTU packet size](#)
- [Secondary IP addresses to an interface](#)
- [Virtual domains](#)
- [Virtual LANs](#)
- [Zones](#)

## Physical

FortiGate units have a number of physical ports where you connect ethernet or optical cables. Depending on the model, they can have anywhere from four to 40 physical ports. Some units have a grouping of ports labelled as internal, providing a built-in switch functionality.

In FortiOS, the port names, as labeled on the FortiGate unit, appear in the web-based manager in the *Unit Operation* widget, found on the Dashboard. They also appear when you are configuring the interfaces, by going to *System > Network > Interface*. As shown below, the FortiGate-100D (Generation 2) has 22 interfaces.

Two of the physical ports on the FortiGate-100D (Generation 2) are SFP ports. These ports share the numbers 15 and 16 with RJ-45 ports. Because of this, when SFP port 15 is used, RJ-45 port 15 cannot be used, and vice versa.

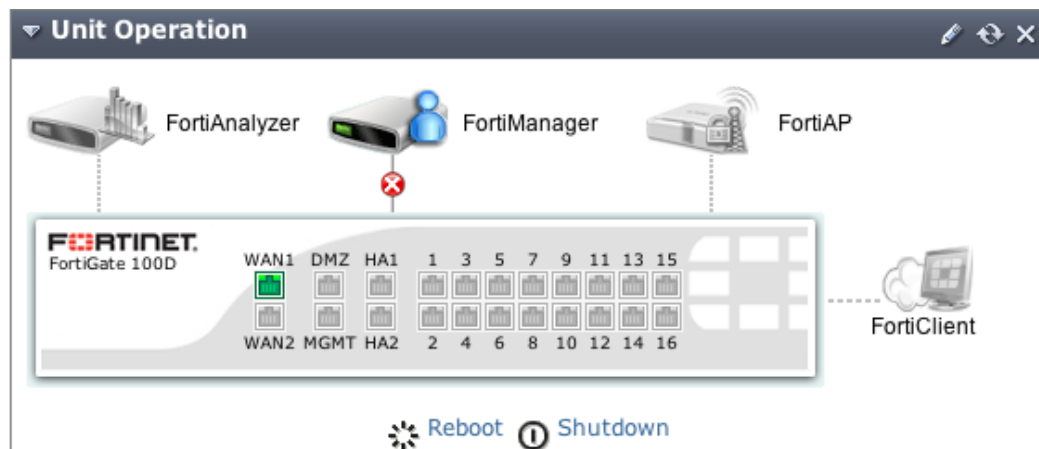

These ports also share the same MAC address.

---

**Figure 235:**FortiGate-100D physical interfaces

**Figure 236:**FortiGate-100D interfaces on the Dashboard

**Figure 237:**Configuring the FortiGate-100D ports

	Name	Type	IP/Netmask	Access	Administrative Status	Link Status	Ref.

Normally the internal interface is configured as a single interface shared by all physical interface connections - a switch. The switch mode feature has two states - switch mode and interface mode. Switch mode is the default mode with only one interface and one address for the entire internal switch. Interface mode enables you to configure each of the internal switch physical interface connections separately. This enables you to assign different subnets and netmasks to each of the internal physical interface connections.

The larger FortiGate units can also include Advanced Mezzanine Cards (AMC), which can provide additional interfaces (Ethernet or optical), with throughput enhancements for more efficient handling of specialized traffic. These interfaces appear in FortiOS as port amc/sw1, amc/sw2 and so on. In the following illustration, the FortiGate-3810A has three AMC cards installed: two single-width (amc/sw1, amc/sw2) and one double-width (amc/dw).

**Figure 238:**FortiGate-3810A AMC card port naming

<input type="checkbox"/>	Name	IP/Netmask	Access	Administrative Status	Link Status
<input type="checkbox"/>	amc-dw2/1	0.0.0.0 / 0.0.0.0		+	+

## Interface settings

In *System > Network > Interface*, you configure the interfaces, physical and virtual, for the FortiGate unit. There are different options for configuring interfaces when the FortiGate unit is in NAT mode or transparent mode. On FortiOS Carrier, you can also enable the Gi gatekeeper on each interface for anti-overbilling.

### Interface page

**Create New** Select to add a new interface, zone or, in transparent mode, port pair.

For more information on configuring zones, see [Zones](#).

Depending on the model you can add a VLAN interface, a loopback interface, a IEEE 802.3ad aggregated interface, or a redundant interface.

When VDOMs are enabled, you can also add Inter-VDOM links.

**Name** The names of the physical interfaces on your FortiGate unit. This includes any alias names that have been configured.

When you combine several interfaces into an aggregate or redundant interface, only the aggregate or redundant interface is listed, not the component interfaces.

If you have added VLAN interfaces, they also appear in the name list, below the physical or aggregated interface to which they have been added.

If you have added loopback interfaces, they also appear in the interface list, below the physical interface to which they have been added. If you have software switch interfaces configured, you will be able to view them. For more information, see [“Software switch” on page 1486](#).

If your FortiGate unit supports AMC modules, the interfaces are named amc-sw1/1, amc-dw1/2, and so on.

**Type** The configuration type for the interface.

<b>IP/Netmask</b>	The current IP address and netmask of the interface.  In VDOM mode, when VDOMs are not all in NAT or transparent mode some values may not be available for display and will be displayed as “-”.
<b>Access</b>	The administrative access configuration for the interface.
<b>Administrative Status</b>	Indicates if the interface can be accessed for administrative purposes. If the administrative status is a green arrow, and administrator could connect to the interface using the configured access.  If the administrative status is a red arrow, the interface is administratively down and cannot be accessed for administrative purposes.
<b>Link Status</b>	The status of the interface physical connection. Link status can be either up (green arrow) or down (red arrow). If link status is up the interface is connected to the network and accepting traffic. If link status is down the interface is not connected to the network or there is a problem with the connection. You cannot change link status from the web-based manager, and typically is indicative of an ethernet cable plugged into the interface.  Link status is only displayed for physical interfaces.
<b>MAC</b>	The MAC address of the interface.
<b>Mode</b>	Shows the addressing mode of the interface. The addressing mode can be manual, DHCP, or PPPoE.
<b>Secondary IP</b>	Displays the secondary IP addresses added to the interface.
<b>MTU</b>	The maximum number of bytes per transmission unit (MTU) for the interface.
<b>Virtual Domain</b>	The virtual domain to which the interface belongs. This column is visible when VDOM configuration is enabled.
<b>VLAN ID</b>	The configured VLAN ID for VLAN subinterfaces.

## Interface configuration and settings

To configure an interface, go to *System > Network > Interface* and select *Create New*.

<b>Name</b>	Enter a name of the interface. Physical interface names cannot be changed.
<b>Alias</b>	Enter an alternate name for a physical interface on the FortiGate unit. This field appears when editing an existing physical interface.  The alias can be a maximum of 25 characters. The alias name will not appears in logs.
<b>Link Status</b>	Indicates whether the interface is connected to a network (link status is <i>Up</i> ) or not (link status is <i>Down</i> ). This field appears when editing an existing physical interface.
<b>Type</b>	Select the type of interface that you want to add.  On some models you can set <i>Type</i> to <i>802.3ad Aggregate</i> or <i>Redundant Interface</i> .

<b>Interface</b>	<p>Displayed when <i>Type</i> is set to <i>VLAN</i>.</p> <p>Select the name of the physical interface to which to add a VLAN interface. Once created, the VLAN interface is listed below its physical interface in the Interface list.</p> <p>You cannot change the physical interface of a VLAN interface except when adding a new VLAN interface.</p>
<b>VLAN ID</b>	<p>Displayed when <i>Type</i> is set to <i>VLAN</i>.</p> <p>Enter the VLAN ID. You cannot change the <i>VLAN ID</i> except when adding a new VLAN interface.</p> <p>The VLAN ID can be any number between 1 and 4094 and must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch connected to the VLAN subinterface.</p>
<b>Virtual Domain</b>	<p>Select the virtual domain to add the interface to.</p> <p>Admin accounts with <i>super_admin</i> profile can change the <i>Virtual Domain</i>.</p>
<b>Physical Interface Members</b>	<p>This section has two different forms depending on the interface type:</p> <ul style="list-style-type: none"> <li>• <b>Software switch interface</b> - this section is a display-only field showing the interfaces that belong to the software switch virtual interface.</li> <li>• <b>802.3ad aggregate or Redundant interface</b> - this section includes available interface and selected interface lists to enable adding or removing interfaces from the interface. For more information, see <a href="#">Redundant interfaces</a>.</li> </ul> <p>Select interfaces from this <i>Available Interfaces</i> list and select the right arrow to add an interface to the <i>Selected Interface</i> list.</p>
<b>Addressing mode</b>	<p>Select the addressing mode for the interface.</p> <ul style="list-style-type: none"> <li>• Select <i>Manual</i> and add an <i>IP/Netmask</i> for the interface. If IPv6 configuration is enabled you can add both a IPv4 and an IPv6 IP address.</li> <li>• Select <i>DHCP</i> to get the interface IP address and other network settings from a DHCP server. For more information, see <a href="#">DHCP addressing mode on an interface</a></li> <li>• Select <i>PPPoE</i> to get the interface IP address and other network settings from a PPPoE server. For more information, see <a href="#">PPPoE addressing mode on an interface</a>.</li> <li>• Select <i>One-Arm Sniffer</i> to enable the interface as a means to detect possible traffic threats. This option is available on physical ports not configured for the primary Internet connection. For more information see <a href="#">One-armed sniffer</a>.</li> <li>• Select <i>Dedicate to FortiAP/FortiSwitch</i> to have a FortiAP unit or FortiSwitch unit connect exclusively to the interface. This option is only available when editing a physical interface, and it has a static IP address. When you enter the IP address, the FortiGate unit automatically creates a DHCP server using the subnet entered. This option is not available on the ADSL interface.</li> </ul> <p>The FortiSwitch option is currently only available on the FortiGate-100D.</p>

<b>IP/Netmask</b>	If <i>Addressing Mode</i> is set to <i>Manual</i> , enter an IPv4 address/subnet mask for the interface. FortiGate interfaces cannot have IP addresses on the same subnet.
<b>IPv6 Address</b>	If <i>Addressing Mode</i> is set to <i>Manual</i> and IPv6 support is enabled, enter an IPv6 address/subnet mask for the interface. A single interface can have both an IPv4 and IPv6 address or just one or the other.
<b>Administrative Access</b>	Select the types of administrative access permitted for IPv4 connections to this interface.
<b>HTTPS</b>	Allow secure HTTPS connections to the web-based manager through this interface. If configured, this option will enable automatically when selecting the <i>HTTP</i> option. For information on this setting, see <a href="#">“HTTPS redirect” on page 1438</a> .
<b>PING</b>	Interface responds to pings. Use this setting to verify your installation and for testing.
<b>HTTP</b>	Allow HTTP connections to the web-based manager through this interface. If configured, this option will also enable the <i>HTTPS</i> option. For information on this setting, see <a href="#">“HTTPS redirect” on page 1438</a> .
<b>SSH</b>	Allow SSH connections to the CLI through this interface.
<b>SNMP</b>	Allow a remote SNMP manager to request SNMP information by connecting to this interface.
<b>TELNET</b>	Allow Telnet connections to the CLI through this interface. Telnet connections are not secure and can be intercepted by a third party.
<b>FMG-Access</b>	Allow FortiManager authorization automatically during the communication exchange between the FortiManager and FortiGate units.
<b>FCT-Access</b>	You can configure a FortiGate interface as an interface that will accept FortiClient connections. When configured, the FortiGate unit sends broadcast messages which the FortiClient software running on a end user PC is listening for.
<b>CAPWAP</b>	Allows the FortiGate unit's wireless controller to manage a wireless access point, such as a FortiAP unit.
<b>IPv6 Administrative Access</b>	Select the types of administrative access permitted for IPv6 connections to this interface. These types are the same as for Administrative Access.
<b>Security Mode</b>	Select a captive portal for the interface. When selected, you can define the portal message and look that the user sees when logging into the interface. You can also define one or more user groups that have access to the interface.
<b>DHCP Server</b>	Select to enable a DHCP server for the interface. For more information on configuring a DHCP server on the interface, see <a href="#">“DHCP servers and relays” on page 1577</a> .
<b>Detect and Identify Devices</b>	Select to enable the interface to be used with BYOD hardware such as iPhones. Define the device definitions by going to <i>User &amp; Device &gt; Device</i> .

<b>Add New Devices to Vulnerability Scan List</b>	This option appears when <i>Detect and Identify Devices</i> is enabled. When enabled, the FortiGate unit performs a network vulnerability scan of any devices detected or seen on the interface. The vulnerability scan occur as configured, either on demand, or as scheduled.
<b>Broadcast Discovery Messages</b>	<p>Available when <i>FCT-Access</i> is enabled for the <i>Administrative Access</i>. Select to enable sends broadcast messages which the FortiClient software running on a end user PC is listening for.</p> <p>Once enabled, the FortiGate unit broadcasts a discovery message that includes the IP address of the interface and listening port number to the local network. All PCs running FortiClient on that network listen for this discovery message.</p>
<b>Enable Explicit Web Proxy</b>	<p>Available when enabling explicit proxy on the <i>System Information</i> Dashboard (<i>System &gt; Dashboard &gt; Status</i>).</p> <p>This option is not available for a VLAN interface selection. Select to enable explicit web proxying on this interface. When enabled, this interface will be displayed on <i>System &gt; Network &gt; Explicit Proxy</i> under <i>Listen on Interfaces</i> and web traffic on this interface will be proxied according to the Web Proxy settings.</p>
<b>Enable STP</b>	With FortiGate units with a switch interface is in switch mode, this option is enabled by default. It enables the single instance MSTP spanning tree protocol.
<b>Listen for RADIUS Accounting Messages</b>	Select to use the interface as a listening port for RADIUS content.
<b>Secondary IP Address</b>	Add additional IPv4 addresses to this interface. Select the Expand Arrow to expand or hide the section.
<b>Comments</b>	Enter a description up to 63 characters to describe the interface.
<b>Administrative Status</b>	<p>Select either <i>Up</i> (green arrow) or <i>Down</i> (red arrow) as the status of this interface.</p> <p><i>Up</i> indicates the interface is active and can accept network traffic.</p> <p><i>Down</i> indicates the interface is not active and cannot accept traffic.</p>
<b>Gi Gatekeeper (FortiOS Carrier only)</b>	For FortiOS Carrier, enable Gi Gatekeeper to enable the Gi firewall as part of the anti-overbilling configuration. You must also configure <i>Gi Gatekeeper Settings</i> by going to <i>System &gt; Admin &gt; Settings</i> .

## Software switch

A software switch, or soft switch, is a virtual switch that is implemented at the software, or firmware level, rather than the hardware level. A software switch can be used to simplify communication between devices connected to different FortiGate interfaces. For example, using a software switch, you can place the FortiGate interface connected to an internal network on the same subnet as your wireless interfaces. Then devices on the internal network can communicate with devices on the wireless network without any additional configuration such as additional security policies, on the FortiGate unit.

It can also be useful if you require more hardware ports on for the switch on a FortiGate unit. For example, if your FortiGate unit has a 4-port switch, WAN1, WAN2 and DMZ interfaces, and you need one more port, you can create a soft switch that can include the 4-port switch and the DMZ interface all on the same subnet. These types of applications also apply to wireless interfaces and virtual wireless interfaces and physical interfaces such as those with FortiWiFi and FortiAP unit.

Similar to a hardware switch, a software switch functions like a single interface. A software switch has one IP address; all of the interfaces in the software switch are on the same subnet. Traffic between devices connected to each interface are not regulated by security policies, and traffic passing in and out of the switch are affected by the same policy.

There are a few things to consider when setting up a software switch:

- Ensure you create a back up of the configuration.
- Ensure you have at least one port or connection such as the console port to connect to the FortiGate unit. If you accidentally combine too many ports, you will need a way to undo any errors.
- The ports that you include must not have any link or relation to any other aspect of the FortiGate unit. For example, DHCP servers, security policies, and so on.
- For increased security, you can create a captive portal for the switch, allowing only specific user groups access to the resources connected to the switch.

#### **To create a software switch - web-based manager**

1. Go to *System > Network > Interface* and select *Create New*.
2. For *Type*, select *Software Switch*.
3. In the *Physical Interface Members* option, select the interfaces to include.
4. Configure the remaining interface settings
5. Select *OK*.

#### **To create a software switch - CLI**

```
config system switch-interface
    edit <switch-name>
        set type switch
        set member <interface_list>
    end
config system interface
    edit <switch_name>
        set ip <ip_address>
        set allowaccess https ssh ping
    end
```

### **Soft switch example**

For this example, the wireless interface (WiFi) needs to be on the same subnet as the DMZ1 interface to facilitate wireless syncing from an iPhone and a local computer. The syncing

between two subnets is problematic. By putting both interfaces on the same subnet the synching will work. The software switch will accomplish this.

In this example, the soft switch includes a wireless interface. Remember to configure any wireless security before proceeding. If you leave this interface open without any password or other security, it leaves open access to not only the wireless interface but to any other interfaces and devices connected within the software switch.

### Clear the interfaces and back up the configuration

First, ensure that the interfaces are not being used with any other security policy or other use on the FortiGate unit. Check the WiFi and DMZ1 ports to ensure DHCP is not enabled on the interface and there are no other dependencies with these interfaces.

Next, save the current configuration, in the event something doesn't work, recovery can be quick.

### Merge the interfaces

The plan is to merge the WiFi port and DMZ1 port. This will create a software switch with a name of "synchro" with an IP address of 10.10.21.12. The steps will create the switch, add the IP and then set the administrative access for HTTPS, SSH and Ping.

#### To merge the interfaces - CLI

```
config system switch-interface
    edit synchro
        set type switch
        set member dmz1 wifi
    end
config system interface
    edit synchro
        set ip 10.10.21.12
        set allowaccess https ssh ping
    end
```

### Final steps

With the switch set up, you can now add security policies, DHCP servers and any other configuration that you would normally do to configure interfaces on the FortiGate unit.

## Virtual Switch

Virtual switch feature enables you create virtual switches on top of the physical switch(es) with designated interfaces/ports so that a virtual switch can build up its forwarding table through learning and forward traffic accordingly. When traffic is forwarded among interfaces belonging to the same virtual switch, the traffic doesn't need to go up to the software stack, but forwarded directly by the switch. When traffic has to be relayed to interfaces not on the virtual switch, the traffic will go through the normal data path and be offloaded to NP4 when possible.

This feature is only available on mid to high end FortiGate units, including the 100D, 600C, 1000C, and 1240B.

**To enable and configure the virtual switch, enter the CLI commands:**

```
config system virtual-switch
edit vs1
    set physical-switch sw0
    config port
        edit 1
            set port port1
            set speed xx
            set duplex xx
            set status [up|down]
        edit 2
            set port port2
            set ...
    end
end
end
```

## Loopback interfaces

A loopback interface is a logical interface that is always up (no physical link dependency) and the attached subnet is always present in the routing table.

The FortiGate's loopback IP address does not depend on one specific external port, and is therefore possible to access it through several physical or VLAN interfaces. Multiple loopback interfaces can be configured in either non-VDOM mode or in each VDOM.

Loopback interfaces still require appropriate firewall policies to allow traffic to and from this type of interface.

A loopback interface can be used with:

- Management access
- BGP (TCP) peering
- PIM RP

Loopback interfaces are a good practice for OSPF. Setting the OSPF router ID the same as loopback IP address troubleshooting OSPF easier, and remembering the management IP addresses (telnet to "router ID").

Dynamic routing protocols can be enabled on loopback interfaces

For black hole static route, use the black hole route type instead of the loopback interface.

## Redundant interfaces

On some models you can combine two or more physical interfaces to provide link redundancy. This feature enables you to connect to two or more switches to ensure connectivity in the event one physical interface or the equipment on that interface fails.

In a redundant interface, traffic is only going over one interface at any time. This differs from an aggregated interface where traffic is going over all interfaces for distribution of increased bandwidth. This difference means redundant interfaces can have more robust configurations with fewer possible points of failure. This is important in a fully-meshed HA configuration.

An interface is available to be in a redundant interface if:

- it is a physical interface, not a VLAN interface
- it is not already part of an aggregated or redundant interface
- it is in the same VDOM as the redundant interface
- it has no defined IP address
- is not configured for DHCP or PPPoE
- it has no DHCP server or relay configured on it
- it does not have any VLAN subinterfaces
- it is not referenced in any security policy, VIP, or multicast policy
- it is not monitored by HA
- it is not one of the FortiGate-5000 series backplane interfaces

When an interface is included in a redundant interface, it is not listed on the *System > Network > Interface* page. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, or routing.

## One-armed sniffer

A one-armed sniffer is used to configure a physical interface on the FortiGate unit as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured IPS sensor and application control list. Matches are logged and then all received traffic is dropped. Sniffing only reports on attacks. It does not deny or otherwise influence traffic.

Using the one-arm sniffer, you can configure a FortiGate unit to operate as an IDS appliance by sniffing network traffic for attacks without actually processing the packets. To configure one-arm IDS, you enable sniffer mode on a FortiGate interface and connect the interface to a hub or to the SPAN port of a switch that is processing network traffic.

To assign an interface as a sniffer interface, go to *System > Network > Interface*, edit the interface and select *One-Arm Sniffer*.

If the check box is not available, the interface is in use. Ensure that the interface is not selected in any firewall policies, routes, virtual IPs or other features in which a physical interface is specified.

<b>Enable Filters</b>	<p>Select to include filters to define a more granular sniff of network traffic. Select specific addresses, ports, VLANs and protocols.</p> <p>In all cases, enter a number, or number range, for the filtering type. For Protocol values, standard protocols are:</p> <ul style="list-style-type: none"><li>• UDP - 17</li><li>• TCP - 6</li><li>• ICMP - 1</li></ul>
<b>Include IPv6 Packets</b>	<p>If your network is running a combination of IPv4 and IPv6 addressing, select to sniff both addressing types. Otherwise, the FortiGate unit will only sniff IPv4 traffic.</p>

<b>Include Non-IP Packets</b>	Select for a more intense scan of content in the traffic.
<b>UTM Security Profiles</b>	IPS sensors, and application control lists enable you to select specific sensors and application you want to identify within the traffic.

## Aggregate Interfaces

Link aggregation (IEEE 802.3ad) enables you to bind two or more physical interfaces together to form an aggregated (combined) link. This new link has the bandwidth of all the links combined. If a link in the group fails, traffic is transferred automatically to the remaining interfaces with the only noticeable effect being a reduced bandwidth.

This is similar to redundant interfaces with the major difference being that a redundant interface group only uses one link at a time, where an aggregate link group uses the total bandwidth of the functioning links in the group, up to eight.

Support of the IEEE standard 802.3ad for link aggregation is available on some models.

An interface is available to be an aggregate interface if:

- it is a physical interface, not a VLAN interface or subinterface
- it is not already part of an aggregate or redundant interface
- it is in the same VDOM as the aggregated interface. Aggregate ports cannot span multiple VDOMs.
- it does not have an IP address and is not configured for DHCP or PPPoE
- it is not referenced in any security policy, VIP, IP Pool or multicast policy
- it is not an HA heartbeat interface
- it is not one of the FortiGate-5000 series backplane interfaces

Some models of FortiGate units do not support aggregate interfaces. In this case, the aggregate option is not an option in the web-based manager or CLI. As well, you cannot create aggregate interfaces from the interfaces in a switch port.

To see if a port is being used or has other dependencies, use the following diagnose command:

```
diagnose sys checkused system.interface.name <interface_name>
```

When an interface is included in an aggregate interface, it is not listed on the *System > Network > Interface* page. Interfaces will still appear in the CLI, although configuration for those interfaces will not take affect. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, IP pools, or routing.

### Example

This example creates an aggregate interface on a FortiGate-3810A using ports 4-6 with an internal IP address of 10.13.101.100, as well as the administrative access to HTTPS and SSH.

#### To create an aggregate interface - web-based manager

1. Go to *System > Network > Interface* and select *Create New*.
2. Enter the Name as *Aggregate*.
3. For the *Type*, select *802.3ad Aggregate*.

If this option does not appear, your FortiGate unit does not support aggregate interfaces.

4. In the *Available Interfaces* list, select port 4, 5 and 6 and move it to the *Selected Interfaces* list.

5. Select the *Addressing Mode* of *Manual*.
6. Enter the IP address for the port of 10.13.101.100/24.
7. For *Administrative Access* select HTTPS and SSH.
8. Select *OK*.

#### To create aggregate interface - CLI

```
config system interface
    edit Aggregate
        set type aggregate
        set member port4 port5 port6
        set vdom root
        set ip 172.20.120.100/24
        set allowaccess https ssh
    end
```

## DHCP addressing mode on an interface

If you configure an interface to use DHCP, the FortiGate unit automatically broadcasts a DHCP request from the interface. The interface is configured with the IP address and any DNS server addresses and default gateway address that the DHCP server provides.

DHCP IPv6 is similar to DHCP IPv4, however there is:

- no default gateway option defined because a host learns the gateway using router advertisement messages
- there is no WINS servers because it is obsolete.

For more information about DHCP IPv6, see RFC 3315.

Configure DHCP for an interface in *System > Network > Interface* and selecting the interface from the list, and selecting *DHCP* in the *Address Mode*. The table describes the DHCP status information when DHCP is configured for an interface.

#### Addressing mode section of New Interface page for DHCP information

<b>Status</b>	<p>Displays DHCP status messages as the interface connects to the DHCP server and gets addressing information. Select <i>Status</i> to refresh the addressing mode status message.</p> <p>Status can be one of:</p> <ul style="list-style-type: none"> <li>• <b>initializing</b> - No activity.</li> <li>• <b>connecting</b> - interface attempts to connect to the DHCP server.</li> <li>• <b>connected</b> - interface retrieves an IP address, netmask, and other settings from the DHCP server.</li> <li>• <b>failed</b> - interface was unable to retrieve an IP address and other settings from the DHCP server.</li> </ul>
<b>Obtained IP/Netmask</b>	The IP address and netmask leased from the DHCP server. Only displayed if <i>Status</i> is <i>connected</i> .
<b>Renew</b>	Select to renew the DHCP license for this interface. Only displayed if <i>Status</i> is <i>connected</i> .

<b>Expiry Date</b>	The time and date when the leased IP address and netmask is no longer valid for the interface. The IP address is returned to the pool to be allocated to the next user request for an IP address. Only displayed if <i>Status</i> is <i>connected</i> .
<b>Default Gateway</b>	The IP address of the gateway defined by the DHCP server. Only displayed if <i>Status</i> is <i>connected</i> , and if <i>Receive default gateway from server</i> is selected.
<b>Distance</b>	Enter the administrative distance for the default gateway retrieved from the DHCP server. The administrative distance, an integer from 1-255, specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route.
<b>Retrieve default gateway from server</b>	Enable to retrieve a default gateway IP address from the DHCP server. The default gateway is added to the static routing table.
<b>Override internal DNS</b>	<p>Enable to use the DNS addresses retrieved from the DHCP server instead of the DNS server IP addresses on the DNS page.</p> <p>When VDOMs are enabled, you can override the internal DNS only on the management VDOM.</p>

## PPPoE addressing mode on an interface

If you configure the interface to use PPPoE, the FortiGate unit automatically broadcasts a PPPoE request from the interface.

The FortiGate units support many PPPoE RFC features (RFC 2516) including unnumbered IPs, initial discovery timeout and PPPoE Active Discovery Terminate (PADT).

PPPoE is only configurable in the web-based manager on desktop FortiGate units. 1U FortiGates and up must be configured in the CLI using the commands:

```
config system interface
    edit <port_name>
        set mode pppoe
        set username <ISP_username>
        set password <ISP_password>
        set idle-timeout <seconds>
        set distance <integer>
        set ipunnumbered <unnumbered-IP>
        set disc-retry-timeout <seconds>
        set padt-retry-timeout <seconds>
        set lcp-echo-interval <seconds>
        set dns-server-override {enable | disable}
    end
```

Configure PPPoE on an interface in *System > Network > Interface*. The table describes the PPPoE status information when PPPoE is configured for an interface.

#### Addressing mode section of New Interface page

<b>Status</b>	<p>Displays PPPoE status messages as the FortiGate unit connects to the PPPoE server and gets addressing information. Select Status to refresh the addressing mode status message.</p> <p>The status is only displayed if you selected <i>Edit</i>.</p> <p>Status can be any one of the following 4 messages.</p>
<b>Initializing</b>	No activity.
<b>Connecting</b>	The interface is attempting to connect to the PPPoE server.
<b>Connected</b>	<p>The interface retrieves an IP address, netmask, and other settings from the PPPoE server.</p> <p>When the status is connected, PPPoE connection information is displayed.</p>
<b>Failed</b>	The interface was unable to retrieve an IP address and other information from the PPPoE server.
<b>Reconnect</b>	<p>Select to reconnect to the PPPoE server.</p> <p>Only displayed if Status is connected.</p>
<b>User Name</b>	The PPPoE account user name.
<b>Password</b>	The PPPoE account password.
<b>Unnumbered IP</b>	Specify the IP address for the interface. If your ISP has assigned you a block of IP addresses, use one of them. Otherwise, this IP address can be the same as the IP address of another interface or can be any IP address.
<b>Initial Disc Timeout</b>	Enter Initial discovery timeout. Enter the time to wait before starting to retry a PPPoE discovery.
<b>Initial PADT timeout</b>	Enter Initial PPPoE Active Discovery Terminate (PADT) timeout in seconds. Use this timeout to shut down the PPPoE session if it is idle for this number of seconds. PADT must be supported by your ISP. Set initial PADT timeout to 0 to disable.
<b>Distance</b>	Enter the administrative distance for the default gateway retrieved from the PPPoE server. The administrative distance, an integer from 1-255, specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route. The default distance for the default gateway is 1.
<b>Retrieve default gateway from server</b>	<p>Enable to retrieve a default gateway IP address from a PPPoE server. The default gateway is added to the static routing table.</p>
<b>Override internal DNS</b>	<p>Enable to replace the DNS server IP addresses on the System DNS page with the DNS addresses retrieved from the PPPoE server.</p> <p>When VDOMs are enabled, you can override the internal DNS only on the management VDOM.</p>

## Administrative access

Interfaces, especially the public-facing ports can be potentially accessed by those who you may not want access to the FortiGate unit. When setting up the FortiGate unit, you can set the type of protocol an administrator must use to access the FortiGate unit. The options include:

- HTTPS
- HTTP
- SSH
- TELNET
- SNMP
- PING
- FortiManager Access (FMG-Access)
- FortiClient Access (FCT-Access)

You can select as many, or as few, even none, that are accessible by an administrator.

This example adds an IPv4 address 172.20.120.100 to the WAN1 interface as well as the administrative access to HTTPS and SSH. As a good practice, set the administrative access when you are setting the IP address for the port.

### To add an IP address on the WAN1 interface - web-based manager

1. Go to *System > Network > Interface*.
2. Select the WAN1 interface row and select *Edit*.
3. Select the *Addressing Mode* of *Manual*.
4. Enter the IP address for the port of 172.20.120.100/24.
5. For *Administrative Access*, select *HTTPS* and *SSH*.
6. Select *OK*.

### To create IP address on the WAN1 interface - CLI

```
config system interface
  edit wan1
    set ip 172.20.120.100/24
    set allowaccess https ssh
  end
```

When adding to, or removing a protocol, you must type the entire list again. For example, if you have an access list of HTTPS and SSH, and you want to add PING, typing:

```
set allowaccess ping
```

...only PING will be set. In this case, you must type...

```
set allowaccess https ssh ping
```

## Wireless

A wireless interface is similar to a physical interface only it does not include a physical connection. The FortiWiFi units enables you to add multiple wireless interfaces that can be available at the same time (the FortiWiFi-30B can only have one wireless interface). On FortiWiFi units, you can configure the device to be either an access point, or a wireless client. As an access point, the FortiWiFi unit can have up to four separate SSIDs, each on their own subnet for wireless access. In client mode, the FortiWiFi only has one SSID, and is used as a receiver, to enable remote users to connect to the existing network using wireless protocols.

Wireless interfaces also require additional security measures to ensure the signal does not get hijacked and data tampered or stolen.

For more information on configuring wireless interfaces see the [Deploying Wireless Networks Guide](#).

## Interface MTU packet size

You can change the maximum transmission unit (MTU) of the packets that the FortiGate unit transmits to improve network performance. Ideally, the MTU should be the same as the smallest MTU of all the networks between the FortiGate unit and the destination of the packets. If the packets that the FortiGate unit sends are larger than the smallest MTU, they are broken up or fragmented, which slows down transmission. You can easily experiment by lowering the MTU to find an MTU size for optimum network performance.

To change the MTU, select Override default MTU value (1500) and enter the MTU size based on the addressing mode of the interface

- 68 to 1 500 bytes for static mode
- 576 to 1 500 bytes for DHCP mode
- 576 to 1 492 bytes for PPPoE mode
- larger frame sizes if supported by the FortiGate model

Only available on physical interfaces. Virtual interfaces associated with a physical interface inherit the physical interface MTU size.

Interfaces on some models support frames larger than the traditional 1500 bytes. Jumbo frames are supported on FortiGate models that have either a SOC2 or NP4lite, except for the FortiGate-30D, as well as on FortiGate-100D series models (for information about your FortiGate unit's hardware, see the [Hardware Acceleration](#) guide). For other models, please contact Fortinet Customer Support for the maximum frame size that is supported.

If you need to enable sending larger frames over a route, you need all Ethernet devices on that route to support that larger frame size, otherwise your larger frames will not be recognized and are dropped.

If you have standard size and larger size frame traffic on the same interface, routing alone cannot route them to different routes based only on frame size. However, you can use VLANs to make sure the larger frame traffic is routed over network devices that support that larger size. VLANs will inherit the MTU size from the parent interface. You will need to configure the VLAN to include both ends of the route as well as all switches and routers along the route.

MTU packet size is changed in the CLI. If you select an MTU size larger than your FortiGate unit supports, an error message will indicate this. In this situation, try a smaller MTU size until the value is supported.

In Transparent mode, if you change the MTU of an interface, you must change the MTU of all interfaces on the FortiGate unit to match the new MTU.

---

To change the MTU size, use the following CLI commands:

```
config system interface
  edit <interface_name>
    set mtu-override enable
    set mtu <byte_size>
  end
```

## Secondary IP addresses to an interface

If an interface is configured with a manual or static IP address, you can also add secondary static IP addresses to the interface. Adding secondary IP addresses effectively adds multiple IP addresses to the interface. Secondary IP addresses cannot be assigned using DHCP or PPPoE.

All of the IP addresses added to an interface are associated with the single MAC address of the physical interface and all secondary IP addresses are in the same VDOM as the interface that are added to. You configure interface status detection for gateway load balancing separately for each secondary IP addresses. As with all other interface IP addresses, secondary IP addresses cannot be on the same subnet as any other primary or secondary IP address assigned to a FortiGate interface unless they are in separate VDOMs.

To configure a secondary IP, go to *System > Network > Interface*, select *Edit* or *Create New* and select the *Secondary IP Address* check box.

## Virtual domains

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. A single FortiGate unit is then flexible enough to serve multiple departments of an organization, separate organizations, or to act as the basis for a service provider's managed security service.

VDOMs provide separate security domains that allow separate zones, user authentication, security policies, routing, and VPN configurations. By default, each FortiGate unit has a VDOM named root. This VDOM includes all of the FortiGate physical interfaces, modem, VLAN subinterfaces, zones, security policies, routing settings, and VPN settings.

When a packet enters a VDOM, it is confined to that VDOM. In a VDOM, you can create security policies for connections between Virtual LAN (VLAN) subinterfaces or zones in the VDOM. Packets do not cross the virtual domain border internally. To travel between VDOMs, a packet must pass through a firewall on a physical interface. The packet then arrives at another VDOM on a different interface, but it must pass through another firewall before entering the VDOM. Both VDOMs are on the same FortiGate unit. Inter-VDOMs change this behavior in that they are internal interfaces; however their packets go through all the same security measures as on physical interfaces.

This example shows how to enable VDOMs on the FortiGate unit and the basic and create a VDOM accounting on the DMZ2 port and assign an administrator to maintain the VDOM. First enable Virtual Domains on the FortiGate unit. When you enable VDOMs, the FortiGate unit will log you out.

For desktop and low-end FortiGate units, VDOMs are enabled using the CLI. On larger FortiGate units, you can enable on the web-based manager or the CLI. Once enabled all further configuration can be made in the web-based manager or CLI.

### To enable VDOMs - web-based manager

1. Go to *System > Dashboard > Status*.

2. In the *System Information* widget, select *Enable* for *Virtual Domain*.

The FortiGate unit logs you out. Once you log back in, you will notice that the menu structure has changed. This reflects the global settings for all Virtual Domains.

#### To enable VDOMs - CLI

```
config system global
    set vdom-admin enable
end
```

Next, add the VDOM called accounting.

#### To add a VDOM - web-based manager

1. Go to *System > VDOM > VDOM*, and select *Create New*.
2. Enter the VDOM name *accounting*.
3. Select *OK*.

To add a VDOM - CLI

```
config vdom
    edit <new_vdom_name>
end
```

With the Virtual Domain created, you can assign a physical interface to it, and assign it an IP address.

#### To assign physical interface to the accounting Virtual Domain - web-based manager

1. Go to *System > Network > Interface*.
2. Select the DMZ2 port row and select *Edit*.
3. For the *Virtual Domain* drop-down list, select *accounting*.
4. Select the *Addressing Mode* of *Manual*.
5. Enter the IP address for the port of 10.13.101.100/24.
6. Set the *Administrative Access* to *HTTPS* and *SSH*.
7. Select *OK*.

#### To assign physical interface to the accounting Virtual Domain - CLI

```
config global
    config system interface
        edit dmz2
            set vdom accounting
            set ip 10.13.101.100/24
            set allowaccess https ssh
        next
    end
```

## Virtual LANs

The term VLAN subinterface correctly implies the VLAN interface is not a complete interface by itself. You add a VLAN subinterface to the physical interface that receives VLAN-tagged packets. The physical interface can belong to a different VDOM than the VLAN, but it must be connected to a network route that is configured for this VLAN. Without that route, the VLAN will not be connected to the network, and VLAN traffic will not be able to access this interface. The traffic on the VLAN is separate from any other traffic on the physical interface.

FortiGate unit interfaces cannot have overlapping IP addresses, the IP addresses of all interfaces must be on different subnets. This rule applies to both physical interfaces and to virtual interfaces such as VLAN subinterfaces. Each VLAN subinterface must be configured with its own IP address and netmask. This rule helps prevent a broadcast storm or other similar network problems.

Any FortiGate unit, with or without VDOMs enabled, can have a maximum of 255 interfaces in Transparent operating mode. In NAT/Route operating mode, the number can range from 255 to 8192 interfaces per VDOM, depending on the FortiGate model. These numbers include VLANs, other virtual interfaces, and physical interfaces. To have more than 255 interfaces configured in Transparent operating mode, you need to configure multiple VDOMs with many interfaces on each VDOM.

This example shows how to add a VLAN, `vlan_accounting` on the FortiGate unit internal interface with an IP address of 10.13.101.101.

#### To add a VLAN - web-based manager

1. Go to *System > Network > Interface* and select *Create New*.

The *Type* is by default set to VLAN.

2. Enter a name for the VLAN to `vlan_accounting`.
3. Select the *Internal* interface.
4. Enter the *VLAN ID*.

The VLAN ID is a number between 1 and 4094 that allow groups of IP addresses with the same VLAN ID to be associated together.

5. Select the *Addressing Mode* of *Manual*.
6. Enter the IP address for the port of 10.13.101.101/24.
7. Set the *Administrative Access* to *HTTPS* and *SSH*.
8. Select *OK*.

#### To add a VLAN - CLI

```
config system interface
  edit VLAN_1
    set interface internal
    set type vlan
    set vlanid 100
    set ip 10.13.101.101/24
    set allowaccess https ssh
  next
end
```

## Zones

Zones are a group of one or more FortiGate interfaces, both physical and virtual, that you can apply security policies to control inbound and outbound traffic. Grouping interfaces and VLAN subinterfaces into zones simplifies the creation of security policies where a number of network segments can use the same policy settings and protection profiles. When you add a zone, you select the names of the interfaces and VLAN subinterfaces to add to the zone. Each interface still has its own address and routing is still done between interfaces, that is, routing is not affected by zones. Security policies can also be created to control the flow of intra-zone traffic.

For example, in the illustration below, the network includes three separate groups of users representing different entities on the company network. While each group has its own set of

port and VLANs, in each area, they can all use the same security policy and protection profiles to access the Internet. Rather than the administrator making nine separate security policies, he can add the required interfaces to a zone, and create three policies, making administration simpler.

**Figure 239:**Network zones

You can configure policies for connections to and from a zone, but not between interfaces in a zone. Using the above example, you can create a security policy to go between zone 1 and zone 3, but not between WAN2 and WAN1, or WAN1 and DMZ1.

This example explains how to set up a zone to include the Internal interface and a VLAN.

#### To create a zone - web-based manager

1. Go to *System > Network > Interface*.
2. Select the arrow on the *Create New* button and select *Zone*.
3. Enter a zone name of *Zone\_1*.
4. Select the Internal interface and the virtual LAN interface *vlan\_accounting* created previously.
5. Select *OK*.

#### To create a zone - CLI

```

config system zone
  edit Zone_1
    set interface internal VLAN_1
  end

```

## Probing Interfaces

Server probes can be used on interfaces. In order for this to occur, the probe response must first be enabled and configured, then the probe response must be allowed administrative access on the interface. Both steps must be done through the CLI.

**Enabling and configuring the probe**

```
config system probe-response
    set http-probe-port <port>
    set http-probe enable
end
```

**Allowing the probe response to have administrative access to the interface**

```
config system interface
    edit <port>
        set allowaccess probe-response
    end
end
```

# Central management

This chapter describes the basics of using FortiManager as an administration tool for multiple FortiGate units. It describes the basics of setting up a FortiGate unit in FortiManager and some key management features you can use within FortiManager to manage the FortiGate unit.

This section includes the topics:

- [Adding a FortiGate to FortiManager](#)
- [Configuration through FortiManager](#)
- [Firmware updates](#)
- [FortiGuard](#)
- [Backup and restore configurations](#)
- [Administrative domains](#)

In order for the FortiGate unit and FortiManager unit to properly connect, both units must have compatible firmware. To find out if your firmware is compatible, refer to the FortiOS or FortiManager Release Notes.

---

## Adding a FortiGate to FortiManager

Before you can maintain a FortiGate unit using a FortiManager unit, you need to add it to the FortiManager. To do this requires configuration on both the FortiGate and FortiManager. This section describes the basics to configure management using a FortiManager device. For more information on the interaction of FortiManager with the FortiGate unit, see the FortiManager documentation.

### FortiGate configuration

These steps ensure that the FortiGate unit will be able to receive updated antivirus and IPS updates and allow remote management through the FortiManager system. You can add a FortiGate unit whether it is running in either NAT mode or transparent mode. The FortiManager unit provides remote management of a FortiGate unit over TCP port 541.

If you have not already done so, register the FortiGate unit by visiting <http://support.fortinet.com> and select *Product Registration*. By registering your Fortinet unit, you will receive updates to threat detection and prevention databases (Antivirus, Intrusion Detection, etc.) and will also ensure your access to technical support.

You must enable the FortiGate management option so the FortiGate unit can accept management updates to firmware, antivirus signatures, and IPS signatures.

#### **To configure the FortiGate unit - web-based manager**

1. Log in to the FortiGate unit.
2. Go to *System > Admin > Settings*.
3. Enter the *IP address* for the FortiManager unit.
4. Select *Send Request*.

The FortiManager ID now appears in the Trusted FortiManager table.

As an additional security measure, you can also select *Registration Password* and enter a password to connect to the FortiManager.

#### To configure the FortiGate unit - CLI

```
config system central-management
    set fmg <ip_address>
end
```

To use the registration password enter:

```
execute central-mgmt register-device
    <fmg-serial-no><fmg-register-password><fgt-username><fgt-password>
```

### Configuring an SSL connection

An SSL connection can be configured between the two devices and an encryption level selected. Use the following CLI commands in the FortiGate CLI to configure the connection:

```
config system central-management
    set status enable
    set enc-algorithm {default* | high | low}
end
```

The default encryption automatically sets high and medium encryption algorithms. Algorithms used for high, medium, and low follows openssl definitions:

- **High** - Key lengths larger than 128 bits, and some cipher suites with 128-bit keys.  
Algorithms are: DHE-RSA-AES256-SHA:AES256-SHA: EDH-RSA-DES-CBC3-SHA: DES-CBC3-SHA:DES-CBC3-MD5:DHE-RSA-AES128-SHA:AES128-SHA
- **Medium** - Key strengths of 128 bit encryption.  
Algorithms are: RC4-SHA:RC4-MD5:RC4-MD
- **Low** - Key strengths of 64 or 56 bit encryption algorithms but excluding export cipher suites  
Algorithms are: EDH-RSA-DES-CBC-SHA; DES-CBC-SHA; DES-CBC-MD5.

### FortiManager configuration

Once the connection between the FortiGate unit and the FortiManager unit has been configured, you can add the FortiGate to the Device Manager in the FortiManager unit's web-based manager.

## Configuration through FortiManager

With the FortiManager system, you can monitor and configure multiple FortiGate units from one location and log in. Using the FortiManager's Device Manager, you can view the FortiGate units and make the usual configuration updates and changes, without having to log in and out of multiple FortiGate units.

FortiManager enables you to complete the configuration, by going to the Device Manager, selecting the FortiGate unit and using the same menu structure and pages as you would see in the FortiGate web-based manager. All changes to the FortiGate configuration are stored locally on the FortiManager unit until you synchronize with the FortiGate unit.

When a FortiGate unit is under control of a FortiManager system, administrators will not be able to change the configuration using the FortiGate. When trying to change options, the unit

displays a message that it is configured through FortiManager, and any changes may be reverted.

## Global objects

If you are maintaining a number of FortiGate units within a network, many of the policies and configuration elements will be the same across the corporation. In these instances, the adding and editing of many of the same policies will become a tedious and error-prone activity. With FortiManager global objects, this level of configuration is simplified.

A global object is an object that is not associated specifically with one device or group. Global objects include security policies, a DNS server, VPN, and IP pools.

The Global Objects window is where you can configure global objects and copy the configurations to the FortiManager device database for a selected device or a group of devices. You can also import configurations from the FortiManager device database for a selected device and modify the configuration as required.

When configuring or creating a global policy object the interface, prompts, and fields are the same as creating the same object on a FortiGate unit using the FortiGate web-based manager.

## Locking the FortiGate web-based manager

When you use the FortiManager to manage multiple FortiGate units, a local FortiGate unit becomes locked from any configuration changes using the web-based manager for most administrators. The `super_admin` will still be able to make changes to the configuration; however, this is not recommended as it may cause conflicts with the FortiManager.

## Firmware updates

A FortiManager unit can also perform firmware updates for multiple FortiGate units, saving time rather than upgrading each FortiGate unit individually.

The FortiManager unit stores local copies of firmware images, either by downloading images from the Fortinet Distribution Network (FDN) or by accepting firmware images that are uploaded from the management computer.

If you are using the FortiManager unit to download firmware images, the FDN first validates device licenses and support contracts and then provides a list of currently available firmware images. For devices with valid Fortinet Technical Support contracts, you can download new firmware images from the FDN and the firmware release notes.

After firmware images have been either downloaded from the FDN or imported to the firmware list, you can either schedule or immediately upgrade/downgrade a device or group of device's firmware.

## FortiGuard

FortiManager can also connect to the FortiGuard Distribution Network (FDN) to receive push updates for IPS signatures and antivirus definitions. These updates can then be used to update multiple FortiGate units throughout an organization. By using the FortiManager as the host for updates, bandwidth use is minimized as updates are downloaded to one source instead of many.

To receive IPS and antivirus updates from FortiManager, indicate an alternate IP address on the FortiGate unit.

### To configure updates from FortiManager

1. Go to *System > Config > FortiGuard*.
2. Select *AntiVirus and IPS Options* to expand the options.
3. Enable both *Allow Push Update* and *Use override push IP*.
4. Enter the IP address of the FortiManager unit.
5. Select *Apply*.

## Backup and restore configurations

FortiManager stores configuration files for backup and restore purposes. FortiManager also enables you to save revisions of configuration files. Configuration backups occur automatically when the administrator logs out, the administrator login session expires, or the FortiGate restarts. Administrators can also start a backup manually.

FortiManager also enables you to view differences between different configurations to view where changes have been made.

Configure the FortiGate as follows to support backing up the configuration to FortiManager:

```
config system central-management
    set mode backup
    set fortimanager-fds-override enable
    set fmg "192.168.206.26"
end
```

On the FortiManager site, the ADOM that includes the FortiGate must be set to backup.

Enabling `fortimanager-fds-override` means that the FortiGate must use the FortiManager for FortiGuard updates and FortiGuard web filtering lookups.

## Administrative domains

FortiManager administrative domains enable the `super_admin` to create groupings of devices for configured administrators to monitor and manage. FortiManager can manage a large number of Fortinet appliances. This enables administrators to maintain managed devices specific to their geographic location or business division. This also includes FortiGate units with multiple configured VDOMs.

Each administrator is tied to an administrative domain (ADOM). When that particular administrator logs in, they see only those devices or VDOMs configured for that administrator and ADOM. The one exception is the `super_admin` account that can see and maintain all administrative domains and the devices within those domains.

Administrative domains are not enabled by default and enabling and configuring the domains can only be performed by the `super_admin`.

The maximum number of administrative domains you can add depends on the FortiManager model.

# Monitoring

With network administration, the first step is installing and configuring the FortiGate unit to be the protector of the internal network. Once the system is running efficiently, the next step is to monitor the system and network traffic, making configuration changes as necessary when a threat or vulnerability is discovered.

This chapter discusses the various methods of monitoring both the FortiGate unit and the network traffic through a range of different tools available within FortiOS.

This section includes the topics:

- [Dashboard](#)
- [sFlow](#)
- [Monitor menus](#)
- [Logging](#)
- [Alert email](#)
- [SNMP](#)

## Dashboard

The FortiOS dashboard provides a location to view real-time system information. By default, the dashboard displays the key statistics of the FortiGate unit itself, providing the memory and CPU status, as well as the health of the ports, whether they are up or down and their throughput.

## Widgets

Within the dashboard is a number of smaller windows, called widgets, that provide this status information. Beyond what is visible by default, you can add a number of other widgets that display other key traffic information including application use, traffic per IP address, top attacks, traffic history and logging statistics.

You can add multiple dashboards to reflect what data you want to monitor, and add the widgets accordingly. Dashboard configuration is only available through the web-based manager. Administrators must have read and write privileges to customize and add widgets when in either menu. Administrators must have read privileges if they want to view the information.

### To add a dashboard and widgets

1. Go to *System > Dashboard*.
2. Select the *Dashboard* menu at the top of the window and select *Add Dashboard*.
3. Enter a name for the widget.
4. Select the *Widget* menu at the top of the window.
5. From the screen, select the type of information you want to add.
6. When done, select the X in the top right of the widget.

Dashboard widgets provide an excellent method to view real-time data about the events occurring on the FortiGate unit and the network. For example, by adding the Network Protocol Usage widget, you can monitor the activity of various protocols over a selected span of time. Based on that information you can add or adjust traffic shaping and/or security policies to control traffic.

## FortiClient software

The *License Information* widget includes information for the FortiClient connections. It displays the number of FortiClient connections allowed and the number of users connecting. By selecting the *Details* link for the number of connections, you can view more information about the connecting user, including IP address, user name, and type of operating system the user is connecting with.

Included with this information is a link for Mac and Windows. Selecting these links automatically downloads the FortiClient install file (.dmg or .exe) to the management computer.

## sFlow

sFlow is a method of monitoring the traffic on your network to identify areas on the network that may impact performance and throughput. FortiOS implements sFlow version 5.

sFlow uses packet sampling to monitor network traffic. The sFlow Agent captures packet information at defined intervals and sends them to an sFlow Collector for analysis, providing real-time data analysis. The information sent is only a sampling of the data for minimal impact on network throughput and performance.

The sFlow Agent is embedded in the FortiGate unit. Once configured, the FortiGate unit sends sFlow datagrams of the sampled traffic to the sFlow Collector, also called an sFlow Analyzer. The sFlow Collector receives the datagrams, and provides real-time analysis and graphing to indicate where potential traffic issues are occurring. sFlow Collector software is available from a number of third party software vendors.

sFlow data captures only a sampling of network traffic, not all traffic like the traffic logs on the FortiGate unit. Sampling works by the sFlow Agent looking at traffic packets when they arrive on an interface. A decision is made whether the packet is dropped and allowed to be to its destination or if a copy is forwarded to the sFlow Collector. The sample used and its frequency are determined during configuration.

sFlow is not supported on virtual interfaces such as vdom link, ipsec, ssl.<vdom> or gre.

The sFlow datagram sent to the Collector contains the information:

- Packet header (e.g. MAC,IPv4,IPv6,IPX,AppleTalk,TCP,UDP, ICMP)
- Sample process parameters (rate, pool etc.)
- Input/output ports
- Priority (802.1p and TOS)
- VLAN (802.1Q)
- Source/destination prefix
- Next hop address
- Source AS, Source Peer AS
- Destination AS Path
- Communities, local preference
- User IDs (TACACS/RADIUS) for source/destination
- URL associated with source/destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

sFlow agents can be added to any type of FortiGate interface. sFlow isn't supported on some virtual interfaces such as VDOM link, IPsec, gre, and ssl.<vdom>.

For more information on sFlow, Collector software and sFlow MIBs, visit [www.sflow.org](http://www.sflow.org).

## Configuration

sFlow configuration is available only from the CLI. Configuration requires two steps: enabling the sFlow Agent and configuring the interface for the sampling information.

### Enable sFlow

```
config system sflow
  set collector-ip <ip_address>
  set collector-port <port_number>
end
```

The default port for sFlow is UDP 6343. To configure in VDOM, use the commands:

```
config system vdom-sflow
  set vdom-sflow enable
  set collector-ip <ip_address>
  set collector-port <port_number>
end
```

Configure sFlow agents per interface.

```
config system interface
  edit <interface_name>
    set sflow-sampler enable
    set sample-rate <every_n_packets>
    set sample-direction [tx | rx | both]
    set polling-interval <seconds>
  end
```

## Monitor menus

The *Monitor* menus enable you to view session and policy information and other activity occurring on your FortiGate unit. The monitors provide the details of user activity, traffic and policy usage to show live activity. Monitors are available for DHCP, routing, security policies, traffic shaping, load balancing, security features, VPN, users, WiFi, and logging.

## Logging

FortiOS provides a robust logging environment that enables you to monitor, store, and report traffic information and FortiGate events, including attempted log ins and hardware status. Depending on your requirements, you can log to a number of different hosts.

To configure logging in the web-based manager, go to *Log & Report > Log Config > Log Settings*.

To configure logging in the CLI use the commands `config log <log_location>`.

For details on configuring logging see the [Logging and Reporting Guide](#).

If you will be using several FortiGate units, you can also use a FortiAnalyzer unit for logging. For more information, see the [FortiAnalyzer Administration Guide](#).

## FortiCloud

The FortiCloud is a subscription-based hosted service. With this service, you can have centralized management, logging, and reporting capabilities available in FortiAnalyzer and FortiManager platforms, without any additional hardware to purchase, install or maintain. In most cases, FortiCloud is the recommended location for saving and viewing logs.

This service includes a full range of reporting, analysis and logging, firmware management and configuration revision history. It is hosted within the Fortinet global FortiGuard Network for maximum reliability and performance, and includes reporting, and drill-down analysis widgets makes it easy to develop custom views of network and security events.

The FortiGate unit sends log messages to the FortiCloud using TCP port 443. Configuration is available once a user account has been set up and confirmed. To enable the account on the FortiGate unit, go to *System > Dashboard > Status*, select *Activate*, and enter the account ID.

For FortiCloud traffic, you can identify a specific port/IP address for logging traffic. Configuration of these services is performed in the CLI, using the command `set source-ip`. When configured, this becomes the dedicated port to send this traffic over.

For example, to set the source IP of the FortiCloud server to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config log fortiguard setting
    set status enable
    set source-ip 192.168.4.5
end
```

From the FortiGate unit, you can configure the connection and sending of log messages to be sent over an SSL tunnel to ensure log messages are sent securely. To do this, use the CLI commands to enable the encrypted connection and define the level of encryption.

```
config log fortiguard setting
    set status enable
    set enc-algorithm {default | high | low | disable}
end
```

For more information on each encryption level see [“Configuring an SSL connection” on page 1511](#).

## FortiGate memory

Logs are saved to the internal memory by default. Inexpensive yet volatile, for basic event logs or verifying traffic, AV or spam patterns, logging to memory is a simple option. However, because logs are stored in the limited space of the internal memory, only a small amount is available for logs. As such logs can fill up and be overridden with new entries, negating the use of recursive data. This is especially true for traffic logs. Also, should the FortiGate unit be shut down or rebooted, all log information will be lost.

## FortiGate hard disk

For those FortiGate units with an internal hard disk or SDHC card, you can store logs to this location. Efficient and local, the hard disk provides a convenient storage location. If you choose to store logs in this manner, remember to backup the log data regularly.

Configure log disk settings is performed in the CLI using the commands:

```
config log disk setting
    set status enable
end
```

Further options are available when enabled to configure log file sizes, and uploading/backup events.

As well, note that the write speeds of hard disks compared to the logging of ongoing traffic may cause the dropping such, it is recommended that traffic logging be sent to a FortiAnalyzer or other device meant to handle large volumes of data.

## Syslog server

An industry standard for collecting log messages, for off-site storage. In the web-based manager, you are able to send logs to a single syslog server, however in the CLI you can configure up to three syslog servers where you can also use multiple configuration options. For example, send traffic logs to one server, antivirus logs to another. The FortiGate unit sends Syslog traffic over UDP port 514. Note that if a secure tunnel is configured for communication to a FortiAnalyzer unit, then Syslog traffic will be sent over an IPSec connection, using UDP 500/4500, protocol IP/50.

To configure a Syslog server in the web-based manager, go to *Log & Report > Log Config > Log Settings*. In the CLI use the commands:

```
config log syslogd setting
    set status enable
end
```

Further options are available when enabled to configure a different port, facility and server IP address.

For Syslog traffic, you can identify a specific port/IP address for logging traffic. Configuration of these services is performed in the CLI, using the command `set source-ip`. When configured, this becomes the dedicated port to send this traffic over.

For example, to set the source IP of a Syslog server to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config log syslogd setting
    set status enable
    set source-ip 192.168.4.5
end
```

## FortiAnalyzer

The FortiAnalyzer family of logging, analyzing, and reporting appliances securely aggregate log data from Fortinet devices and other syslog-compatible devices. Using a comprehensive suite of easily-customized reports, users can filter and review records, including traffic, event, virus, attack, Web content, and email data, mining the data to determine your security stance and assure regulatory compliance. FortiAnalyzer also provides advanced security management functions such as quarantined file archiving, event correlation, vulnerability assessments, traffic analysis, and archiving of email, Web access, instant messaging and file transfer content.

The FortiGate unit sends log messages over UDP port 514 or OFTP (TCP 514). If a secure connection has been configured, log traffic is sent over UDP port 500/4500, Protocol IP/50. For more information on configuring a secure connection see [“Sending logs using a secure connection” on page 1511](#).

For FortiAnalyzer traffic, you can identify a specific port/IP address for logging traffic. Configuration of these services is performed in the CLI, using the command `set source-ip`. When configured, this becomes the dedicated port to send this traffic over.

For example, to set the source IP of a FortiAnalyzer unit to be on port 3 with an IP of 192.168.21.12, the commands are:

```
config log fortiguard setting
    set status enable
    set source-ip 192.168.21.12
end
```

## Sending logs using a secure connection

From the FortiGate unit, you can configure the connection and sending of log messages over an SSL tunnel to ensure log messages are sent securely. To do this, use the CLI commands below to enable the encrypted connection and define the level of encryption.

You must configure the secure tunnel on **both** ends of the tunnel, the FortiGate unit and the FortiAnalyzer unit.

This configuration is for FortiAnalyzer OS version 4.0 MR2 or lower. For version 4.0 MR3, see [“Configuring an SSL connection” on page 1511](#).

### To configure a secure connection to the FortiAnalyzer unit

On the FortiAnalyzer unit, enter the commands:

```
config log device
    edit <device_name>
        set secure psk
        set psk <name_of_IPSec_tunnel>
        set id <fortigate_device_name_on_the_fortianalyzer>
    end
```

### To configure a secure connection on the FortiGate unit

On the FortiGate CLI, enter the commands:

```
config log fortianalyzer setting
    set status enable
    set server <ip_address>
    set local
    set localid <name_of_IPSec_tunnel>
end
```

## Configuring an SSL connection

An SSL connection can be configured between the two devices, and an encryption level selected.

Use the CLI commands to configure the encryption connection:

```
config log fortianalyzer setting
    set status enable
    set enc-algorithm {default* | high | low | disable}
end
```

The default encryption automatically sets high and medium encryption algorithms. Algorithms used for high, medium, and low follows openssl definitions:

- **High** - Key lengths larger than 128 bits, and some cipher suites with 128-bit keys.  
Algorithms are: DHE-RSA-AES256-SHA:AES256-SHA: EDH-RSA-DES-CBC3-SHA: DES-CBC3-SHA:DES-CBC3-MD5:DHE-RSA-AES128-SHA:AES128-SHA
- **Medium** - Key strengths of 128 bit encryption.  
Algorithms are: RC4-SHA:RC4-MD5:RC4-MD
- **Low** - Key strengths of 64 or 56 bit encryption algorithms but excluding export cipher suites  
Algorithms are: EDH-RSA-DES-CBC-SHA; DES-CBC-SHA; DES-CBC-MD5.

If you want to use an IPSec tunnel to connect to the FortiAnalyzer unit, you need to first disable the enc-algorithm:

```
config log fortianalyzer setting
    set status enable
    set enc-algorithm disable
```

Then set the IPSec encryption:

```
set encrypt enable
    set psksecret <preshared_IPSec_tunnel_key>
end
```

## Packet Capture

When troubleshooting networks, it helps to look inside the header of the packets. This helps to determine if the packets, route, and destination are all what you expect. Packet capture can also be called a network tap, packet sniffing, or logic analyzing.

### To use the packet capture.

1. Go to *System > Network > Packet Capture*.
2. Select the interface to monitor and select the number of packets to keep.
3. Select *Enable Filters*.
4. Enter the information you want to gather from the packet capture.
5. Select *OK*.

To run the capture, select the play button in the progress column in the packet capture list. If not active, *Not Running* will also appear in the column cell. The progress bar will indicate the status of the capture. You can stop and restart it at any time.

When the capture is complete, select the *Download* icon to save the packet capture file to your hard disk for further analysis.

Packet capture tells you what is happening on the network at a low level. This can be very useful for troubleshooting problems, such as:

- finding missing traffic
- seeing if sessions are setting up properly
- locating ARP problems such as broadcast storm sources and causes
- confirming which address a computer is using on the network if they have multiple addresses or are on multiple networks
- confirming routing is working as you expect
- wireless client connection problems

- intermittent missing PING packets
- a particular type of packet is having problems, such as UDP, which is commonly used for streaming video

If you are running a constant traffic application such as ping, packet capture can tell you if the traffic is reaching the destination, how the port enters and exits the FortiGate unit, if the ARP resolution is correct, and if the traffic is returning to the source as expected. You can also use packet switching to verify that NAT or other configuration is translating addresses or routing traffic the way that you want it to.

Before you start capturing packets, you need to have a good idea of what you are looking for. Capture is used to confirm or deny your ideas about what is happening on the network. If you try capture without a plan to narrow your search, you could end up with too much data to effectively analyze. On the other hand, you need to capture enough packets to really understand all of the patterns and behavior that you are looking for.

## Alert email

As an administrator, you want to be certain you can respond quickly to issues occurring on your network or on the FortiGate unit. Alert emails provide an efficient and direct method of notifying an administrator of events. By configuring alert messages, you can define the threshold when a problem becomes critical and needs attention. When this threshold is reached, the FortiGate unit will send an email to one or more individuals, notifying them of the issue.

In the following example, the FortiGate unit is configured to send email to two administrators (admin1 and admin2) when multiple intrusions are detected every two minutes. The FortiGate unit has its own email address on the mail server.

### To configure the email service

1. Go to *System > Config > Messaging Servers*.
2. Complete the following and select *Apply*:

<b>SMTP Server</b>	Enter the address or name of the email server. For example, <code>smtp.example.com</code> .
<b>Default Reply To</b>	Enter an email address to associate with the alert email. This field is optional. If you enter an email address here, it overrides the email address entered when configuring alert email in <i>Log &amp; Report &gt; Alert E-mail</i> .
<b>Authentication</b>	Enable authentication if required by the email server.
<b>SMTP User</b>	FortiGate
<b>Password</b>	*****

### To configure alert email - web-based manager

1. Go to *Log & Report > Log Config > Alert E-mail*.
2. Enter the information:

<b>Email from</b>	fortigate@example.com
<b>Email to</b>	admin1@example.com admin2@example.com

3. For the *Interval Time*, enter 2.
4. Select *Intrusion Detected*.
5. Select *Apply*.

#### To configure alert email - CLI

```
config system email-server
    set port 25
    set server smtp.example.com
    set authenticate enable
    set username FortiGate
    set password *****
end
config alertemail setting
    set username fortigate@example.com
    set mailto1 admin1@example.com
    set mailto2 admin2@example.com
    set filter category
    set IPS-logs enable
end
```

## SNMP

Simple Network Management Protocol (SNMP) enables you to monitor hardware on your network. You can configure the hardware, such as the FortiGate SNMP agent, to report system information and send traps (alarms or event messages) to SNMP managers. An SNMP manager, or host, is typically a computer running an application that can read the incoming trap and event messages from the agent and send out SNMP queries to the SNMP agents. A FortiManager unit can act as an SNMP manager to one or more FortiGate units. FortiOS supports SNMP using IPv4 and IPv6 addressing.

By using an SNMP manager, you can access SNMP traps and data from any FortiGate interface or VLAN subinterface configured for SNMP management access. Part of configuring an SNMP manager is to list it as a host in a community on the FortiGate unit it will be monitoring. Otherwise, the SNMP monitor will not receive any traps from that FortiGate unit or be able to query that unit.

The FortiGate SNMP implementation is read-only. SNMP v1, v2c, and v3 compliant SNMP managers have read-only access to FortiGate system information through queries and can receive trap messages from the FortiGate unit.

To monitor FortiGate system information and receive FortiGate traps, you must first compile the Fortinet and FortiGate Management Information Base (MIB) files. A MIB is a text file that describes a list of SNMP data objects that are used by the SNMP manager. These MIBs provide information the SNMP manager needs to interpret the SNMP trap, event, and query messages sent by the FortiGate unit SNMP agent.

FortiGate core MIB files are available for download by going to *System > Config > SNMP* and selecting the download link on the page.

The Fortinet implementation of SNMP includes support for most of RFC 2665 (Ethernet-like MIB) and most of RFC 1213 (MIB II). For more information, see [“Fortinet MIBs” on page 1520](#). RFC support for SNMP v3 includes Architecture for SNMP Frameworks (RFC 3411), and partial support of User-based Security Model (RFC 3414).

SNMP traps alert you to events that occur such as an a full log disk or a virus detected.

SNMP fields contain information about the FortiGate unit, such as CPU usage percentage or the number of sessions. This information is useful for monitoring the condition of the unit on an ongoing basis and to provide more information when a trap occurs.

The FortiGate SNMP v3 implementation includes support for queries, traps, authentication, and privacy. Authentication and encryption are configured in the CLI. See the `system snmp user` command in the [FortiGate CLI Reference](#).

## SNMP configuration settings

Before a remote SNMP manager can connect to the FortiGate agent, you must configure one or more FortiGate interfaces to accept SNMP connections by going to *System > Network > Interface*. Select the interface and, in the *Administrative Access*, select *SNMP*.

For VDOMS, SNMP traps can only be sent on interfaces in the management VDOM. Traps cannot be sent over other interfaces outside the management VDOM.

To configure SNMP settings, go to *System > Config > SNMP*.

<b>SNMP Agent</b>	Select to enable SNMP communication.
<b>Description</b>	Enter descriptive information about the FortiGate unit. The description can be up to 35 characters.
<b>Location</b>	Enter the physical location of the FortiGate unit. The system location description can be up to 35 characters long.
<b>Contact</b>	Enter the contact information for the person responsible for this FortiGate unit. The contact information can be up to 35 characters.

### SNMP v1/v2c section

To create a new SNMP community, see [New SNMP Community page](#).

<b>Community Name</b>	The name to identify the community.
<b>Queries</b>	Indicates whether queries protocols (v1 and v2c) are enabled or disabled. A green check mark indicates queries are enabled; a gray x indicates queries are disabled. If one query is disabled and another one enabled, there will still be a green check mark.
<b>Traps</b>	Indicates whether trap protocols (v1 and v2c) are enabled or disabled. A green check mark indicates traps are enabled; a gray x indicates traps are disabled. If one query is disabled and another one enabled, there will still be a green check mark.
<b>Enable</b>	Select the check box to enable or disable the community.

### SNMP v3 section

To create a new SNMP community, see [Create New SNMP V3 User](#).

<b>User Name</b>	The name of the SNMPv3 user.
<b>Security Level</b>	The security level of the user.
<b>Notification Host</b>	The IP address or addresses of the host.
<b>Queries</b>	Indicates whether queries are enabled or disabled. A green check mark indicates queries are enabled; a gray x indicates queries are disabled

---

### ***New SNMP Community page***

---

<b>Community Name</b>	Enter a name to identify the SNMP community
-----------------------	---

---

#### **Hosts (section)**

---

<b>IP Address</b>	Enter the IP address and Identify the SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit.  You can also set the IP address to 0.0.0.0 to so that any SNMP manager can use this SNMP community.
-------------------	--

---

<b>Interface</b>	Optionally, select the name of the interface that this SNMP manager uses to connect to the FortiGate unit. You only have to select the interface if the SNMP manager is not on the same subnet as the FortiGate unit. This can occur if the SNMP manager is on the Internet or behind a router.  In virtual domain mode, the interface must belong to the management VDOM to be able to pass SNMP traps.
------------------	--

---

<b>Delete</b>	Removes an SNMP manager from the list within the <i>Hosts</i> section.
---------------	--

---

<b>Add</b>	Select to add a blank line to the Hosts list. You can add up to eight SNMP managers to a single community.
------------	--

---

#### **Queries (section)**

---

<b>Protocol</b>	The SNMP protocol. In the v1 row, this means that the settings are for SNMP v1. In the v2c row, this means that the settings are for SNMP v2c.
-----------------	--

---

<b>Port</b>	Enter the port number (161 by default) that the SNMP managers in this community use for SNMP v1 and SNMP v2c queries to receive configuration information from the FortiGate unit. Select the <i>Enable</i> check box to activate queries for each SNMP version.  <b>Note:</b> The SNMP client software and the FortiGate unit must use the same port for queries.
-------------	--

---

<b>Enable</b>	Select to enable that SNMP protocol.
---------------	--------------------------------------

---

#### **Traps (section)**

---

<b>Protocol</b>	The SNMP protocol. In the v1 row, this means that the settings are for SNMP v1. In the v2c row, this means that the settings are for SNMP v2c.
-----------------	--

---

<b>Local</b>	Enter the remote port numbers (port 162 for each by default) that the FortiGate unit uses to send SNMP v1 or SNMP v2c traps to the SNMP managers in this community. Select the <i>Enable</i> check box to activate traps for each SNMP version.  <b>Note:</b> The SNMP client software and the FortiGate unit must use the same port for traps.
--------------	---

---

<b>Remote</b>	Enter the remote port number (port 162 is default) that the FortiGate unit uses to send SNMP v1 or v2c traps to the SNMP managers in this community.  <b>Note:</b> The SNMP client software and the FortiGate unit must use the same port for queries.
---------------	--

---

<b>Enable</b>	Select to activate traps for each SNMP version.
<b>SNMP Event</b>	<p>Enable each SNMP event for which the FortiGate unit should send traps to the SNMP managers in this community.</p> <p><i>CPU Over usage</i> traps sensitivity is slightly reduced, by spreading values out over 8 polling cycles. This prevents sharp spikes due to CPU intensive short-term events such as changing a policy.</p> <p><i>Power Supply Failure</i> event trap is available only on some models.</p> <p><i>AMC interfaces enter bypass mode</i> event trap is available only on models that support AMC modules.</p>
<b>Enable</b>	Select to enable the SNMP event.
<b>Create New SNMP V3 User</b>	
<b>User Name</b>	Enter the name of the user.
<b>Security Level</b>	Select the type of security level the user will have.
<b>Notification Host</b>	Enter the IP address of the notification host. If you want to add more than one host, after entering the IP address of the first host, select the plus sign to add another host.
<b>Enable Query</b>	Select to enable or disable the query. By default, the query is enabled.
<b>Port</b>	Enter the port number in the field.
<b>Events</b>	Select the SNMP events that will be associated with that user.

## Gigabit interfaces

When determining the interface speed of a FortiGate unit with a 10G interface, the IF-MIB.ifSpeed may not return the correct value. IF-MIB.ifSpeed is a 32-bit gauge used to report interface speeds in bits/second and cannot convert to a 64-bit value. The 32-bit counter wrap the output too fast to be accurate.

In this case, you can use the value ifHighSpeed. It reports interface speeds in megabits/second. This ensures that 10Gb interfaces report the correct value.

## SNMP agent

You need to first enter information and enable the FortiGate SNMP Agent. Enter information about the FortiGate unit to identify it so that when your SNMP manager receives traps from the FortiGate unit, you will know which unit sent the information.

### To configure the SNMP agent - web-based manager

1. Go to *System > Config > SNMP*.
2. Select *Enable* for the *SNMP Agent*.
3. Enter a descriptive name for the agent.
4. Enter the location of the FortiGate unit.
5. Enter a contact or administrator for the SNMP Agent or FortiGate unit.
6. Select *Apply*.

### To configure SNMP agent - CLI

```
config system snmp sysinfo
  set status enable
  set contact-info <contact_information>
  set description <description_of_FortiGate>
  set location <FortiGate_location>
end
```

## SNMP community

An SNMP community is a grouping of devices for network administration purposes. Within that SNMP community, devices can communicate by sending and receiving traps and other information. One device can belong to multiple communities, such as one administrator terminal monitoring both a firewall SNMP and a printer SNMP community.

Add SNMP communities to your FortiGate unit so that SNMP managers can connect to view system information and receive SNMP traps.

You can add up to three SNMP communities. Each community can have a different configuration for SNMP queries and traps. Each community can be configured to monitor the FortiGate unit for a different set of events. You can also add the IP addresses of up to 8 SNMP managers to each community.

When the FortiGate unit is in virtual domain mode, SNMP traps can only be sent on interfaces in the management virtual domain. Traps cannot be sent over other interfaces.

### To add an SNMP v1/v2c community - web-based manager

1. Go to *System > Config > SNMP*.
2. In the *SNMP v1/v2c* area, select *Create New*.
3. Enter a *Community Name*.
4. Enter the IP address and identify the SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit.
5. Select the interface if the SNMP manager is not on the same subnet as the FortiGate unit.
6. Enter the *Port* number that the SNMP managers in this community use for SNMP v1 and SNMP v2c queries to receive configuration information from the FortiGate unit. Select the *Enable* check box to activate queries for each SNMP version.
7. Enter the Local and Remote port numbers that the FortiGate unit uses to send SNMP v1 and SNMP v2c traps to the SNMP managers in this community.
8. Select the *Enable* check box to activate traps for each SNMP version.
9. Select *OK*.

### To add an SNMP v1/v2c community - CLI

```
config system snmp community
  edit <index_number>
    set events <events_list>
    set name <community_name>
    set query-v1-port <port_number>
    set query-v1-status {enable | disable}
    set query-v2c-port <port_number>
    set query-v2c-status {enable | disable}
    set status {enable | disable}
    set trap-v1-lport <port_number>
    set trap-v1-rport <port_number>
    set trap-v1-status {enable | disable}
    set trap-v2c-lport <port_number>
    set trap-v2c-rport <port_number>
    set trap-v2c-status {enable | disable}
  end
```

### To add an SNMP v3 community - web-based manager

1. Go to *System > Config > SNMP*.
2. In the *SNMP v3* area, select *Create New*.
3. Enter a *User Name*.
4. Select a *Security Level* and associated authorization algorithms.
5. Enter the IP address of the *Notification Host* SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit.
6. Enter the *Port* number that the SNMP managers in this community use to receive configuration information from the FortiGate unit. Select the *Enable* check box to activate queries for each SNMP version.
7. Select the *Enable* check box to activate traps.
8. Select *OK*.

### To add an SNMP v3 community - CLI

```
config system snmp user
  edit <index_number>
    set security-level [auth-priv | auth-no-priv | no-auth-no-priv]
    set queries enable
    set query-port <port_number>
    set notify-hosts <ip_address>
    set events <event_selections>
  end
```

## Enabling on the interface

Before a remote SNMP manager can connect to the FortiGate agent, you must configure one or more FortiGate interfaces to accept SNMP connections.

### To configure SNMP access - web-based manager

1. Go to *System > Network > Interface*.
2. Choose an interface that an SNMP manager connects to and select *Edit*.

3. In *Administrative Access*, select *SNMP*.

4. Select *OK*.

#### To configure SNMP access - CLI

```
config system interface
    edit <interface_name>
        set allowaccess snmp
    end
```

If the interface you are configuring already has protocols that are allowed access, use the command `append allowaccess snmp` instead, or else the other protocols will be replaced. For more information, see [“Adding and removing options from lists” on page 1417](#).

---

## Fortinet MIBs

The FortiGate SNMP agent supports Fortinet proprietary MIBs as well as standard RFC 1213 and RFC 2665 MIBs. RFC support includes support for the parts of RFC 2665 (Ethernet-like MIB) and the parts of RFC 1213 (MIB II) that apply to FortiGate unit configuration.

There are two MIB files for FortiGate units - the Fortinet MIB, and the FortiGate MIB. The Fortinet MIB contains traps, fields and information that is common to all Fortinet products. The FortiGate MIB contains traps, fields and information that is specific to FortiGate units. Each Fortinet product has its own MIB. If you use other Fortinet products you will need to download their MIB files as well. Both MIB files are used for FortiOS and FortiOS Carrier; there are no additional traps for the Carrier version of the operating system.

The Fortinet MIB and FortiGate MIB along with the two RFC MIBs are listed in tables in this section. You can download the two FortiGate MIB files from Fortinet Customer Support. The Fortinet MIB contains information for Fortinet products in general. the Fortinet FortiGate MIB includes the system information for The FortiGate unit and version of FortiOS. Both files are required for proper SNMP data collection.

To download the MIB files, go to *System > Config > SNMP* and select a MIB link in the *FortiGate SNMP MIB* section.

Your SNMP manager may already include standard and private MIBs in a compiled database that is ready to use. You must add the Fortinet proprietary MIB to this database to have access to the Fortinet specific information.

There were major changes to the MIB files between v3.0 and v4.0. You need to use the new MIBs for v4.0 or you may mistakenly access the wrong traps and fields.

MIB files are updated for each version of FortiOS. When upgrading the firmware ensure that you updated the Fortinet FortiGate MIB file as well.

---

**Table 68:** Fortinet MIBs

MIB file name or RFC	Description
<b>FORTINET-CORE-MIB.mib</b>	<p>The Fortinet MIB includes all system configuration information and trap information that is common to all Fortinet products.</p> <p>Your SNMP manager requires this information to monitor FortiGate unit configuration settings and receive traps from the FortiGate SNMP agent.</p>
<b>FORTINET-FORTIGATE-MIB.mib</b>	<p>The FortiGate MIB includes all system configuration information and trap information that is specific to FortiGate units.</p> <p>Your SNMP manager requires this information to monitor FortiGate configuration settings and receive traps from the FortiGate SNMP agent. FortiManager systems require this MIB to monitor FortiGate units.</p>
<b>RFC-1213 (MIB II)</b>	<p>The FortiGate SNMP agent supports MIB II groups with these exceptions.</p> <ul style="list-style-type: none"> <li>• No support for the EGP group from MIB II (RFC 1213, section 3.11 and 6.10).</li> <li>• Protocol statistics returned for MIB II groups (IP/ICMP/TCP/UDP/etc.) do not accurately capture all FortiGate traffic activity. More accurate information can be obtained from the information reported by the Fortinet MIB.</li> </ul>
<b>RFC-2665 (Ethernet-like MIB)</b>	<p>The FortiGate SNMP agent supports Ethernet-like MIB information. FortiGate SNMP does not support for the dot3Tests and dot3Errors groups.</p>

## SNMP get command syntax

Normally, to get configuration and status information for a FortiGate unit, an SNMP manager would use an SNMP get commands to get the information in a MIB field. The SNMP get command syntax would be similar to:

```
snmpget -v2c -c <community_name> <address_ipv4> {<OID> | <MIB_field>}
```

...where...

<community\_name> is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. The most commonly used community name is `public`.

<address\_ipv4> is the IP address of the FortiGate interface that the SNMP manager connects to.

{<OID> | <MIB\_field>} is the object identifier (OID) for the MIB field or the MIB field name itself.

The SNMP `get` command gets firmware version running on the FortiGate unit. The community name is `public`. The IP address of the interface configured for SNMP management access is `10.10.10.1`. The firmware version MIB field is `fgSysVersion` and the OID for this MIB field is

1.3.6.1.4.1.12356.101.4.1.1 The first command uses the MIB field name and the second uses the OID:

```
snmpget -v2c -c public 10.10.10.1 fgSysVersion.0  
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.4.1.1.0
```

The OIDs and object names used in these examples are dependent on the version of MIB and are subject to change.

---

# VLANs

Virtual Local Area Networks (VLANs) multiply the capabilities of your FortiGate unit, and can also provide added network security. Virtual LANs (VLANs) use ID tags to logically separate devices on a network into smaller broadcast domains. These smaller domains forward packets only to devices that are part of that VLAN domain. This reduces traffic and increases network security.

A Local Area Network (LAN) is a group of connected computers and devices that are arranged into network broadcast domains. A LAN broadcast domain includes all the computers that receive a packet broadcast from any computer in that broadcast domain. A switch will automatically forward the packets to all of its ports; in contrast, routers do not automatically forward network broadcast packets. This means routers separate broadcast domains. If a network has only switches and no routers, that network is considered one broadcast domain, no matter how large or small it is. Smaller broadcast domains are more efficient because fewer devices receive unnecessary packets. They are more secure as well because a hacker reading traffic on the network will have access to only a small portion of the network instead of the entire network's traffic.

Virtual LANs (VLANs) use ID tags to logically separate a LAN into smaller broadcast domains. Each VLAN is its own broadcast domain. Smaller broadcast domains reduce traffic and increase network security. The IEEE 802.1Q standard defines VLANs. All layer-2 and layer-3 devices along a route must be 802.1Q-compliant to support VLANs along that route. For more information, see [“VLAN switching and routing” on page 1524](#) and [“VLAN layer-3 routing” on page 1527](#).

VLANs reduce the size of the broadcast domains by only forwarding packets to interfaces that are part of that VLAN or part of a VLAN trunk link. Trunk links form switch-to-switch or switch-to-router connections, and forward traffic for all VLANs. This enables a VLAN to include devices that are part of the same broadcast domain, but physically distant from each other.

VLAN ID tags consist of a 4-byte frame extension that switches and routers apply to every packet sent and received in the VLAN. Workstations and desktop computers, which are commonly originators or destinations of network traffic, are not an active part of the VLAN process. All the VLAN tagging and tag removal is done after the packet has left the computer. For more information, see [“VLAN ID rules” on page 1524](#).

Any FortiGate unit without VDOMs enabled can have a maximum of 255 interfaces in transparent operating mode. The same is true for any single VDOM. In NAT mode, the number can range from 255 to 8192 interfaces per VDOM, depending on the FortiGate model. These numbers include VLANs, other virtual interfaces, and physical interfaces. To have more than 255 interfaces configured in transparent operating mode, you need to configure multiple VDOMs that enable you to divide the total number of interfaces over all the VDOMs.

One example of an application of VLANs is a company's accounting department. Accounting computers may be located at both main and branch offices. However, accounting computers need to communicate with each other frequently and require increased security. VLANs allow the accounting network traffic to be sent only to accounting computers and to connect accounting computers in different locations as if they were on the same physical subnet.

This guide uses the term “packet” to refer to both layer-2 frames and layer-3 packets.

## VLAN ID rules

Layer-2 switches and layer-3 devices add VLAN ID tags to the traffic as it arrives and remove them before they deliver the traffic to its final destination. Devices such as PCs and servers on the network do not require any special configuration for VLANs. Twelve bits of the 4-byte VLAN tag are reserved for the VLAN ID number. Valid VLAN ID numbers are from 1 to 4094, while 0 is used for high priority frames, and 4095 is reserved.

On a layer-2 switch, you can have only one VLAN subinterface per physical interface, unless that interface is configured as a trunk link. Trunk links can transport traffic for multiple VLANs to other parts of the network.

On a FortiGate unit, you can add multiple VLANs to the same physical interface. However, VLAN subinterfaces added to the same physical interface cannot have the same VLAN ID or have IP addresses on the same subnet. You can add VLAN subinterfaces with the same VLAN ID to different physical interfaces.

Creating VLAN subinterfaces with the same VLAN ID does not create any internal connection between them. For example a VLAN ID of 300 on port1 and VLAN ID of 300 on port2 are allowed, but they are not connected. Their relationship is the same as between any two FortiGate network interfaces.

## VLAN switching and routing

VLAN switching takes place on the OSI model layer-2, just like other network switching. VLAN routing takes place on the OSI model layer-3. The difference between them is that during VLAN switching, VLAN packets are simply forwarded to their destination. This is different from VLAN routing where devices can open the VLAN packets and change their VLAN ID tags to route the packets to a new destination.

### VLAN layer-2 switching

Ethernet switches are layer-2 devices, and generally are 802.1Q compliant. Layer 2 refers to the second layer of the seven layer Open Systems Interconnect (OSI) basic networking model; the Data Link layer. FortiGate units act as layer-2 switches or bridges when they are in transparent mode. The units simply tag and forward the VLAN traffic or receive and remove the tags from the packets. A layer-2 device does not inspect incoming packets or change their contents; it only adds or removes tags and routes the packet.

A VLAN can have any number of physical interfaces assigned to it. Multiple VLANs can be assigned to the same physical interface. Typically two or more physical interfaces are assigned to a VLAN, one for incoming and one for outgoing traffic. Multiple VLANs can be configured on one FortiGate unit, including trunk links.

### Layer-2 VLAN example

To better understand VLAN operation, this example shows what happens to a data frame on a network that uses VLANs.

The network topology consists of two 8-port switches that are configured to support VLANs on a network. Both switches are connected through port 8 using an 802.1Q trunk link. Subnet 1 is connected to switch A, and subnet 2 is connected to switch B. The ports on the switches are configured as follows.

**Table 69:** How ports and VLANs are used on Switch A and B

Switch	Ports	VLAN
A	1 - 4	100
A	5 - 7	200
A & B	8	Trunk link
B	4 - 5	100
B	6	200

In this example, switch A is connected to the Branch Office and switch B to the Main Office.

1. A computer on port 1 of switch A sends a data frame over the network.
2. Switch A tags the data frame with a VLAN 100 ID tag upon arrival because port 1 is part of VLAN 100.
3. Switch A forwards the tagged data frame to the other VLAN 100 ports — ports 2 through 4. Switch A also forwards the data frame to the 802.1Q trunk link (port 8) so other parts of the network that may contain VLAN 100 groups will receive VLAN 100 traffic.

This data frame is not forwarded to the other ports on switch A because they are not part of VLAN 100. This increases security and decreases network traffic.

4. Switch B receives the data frame over the trunk link (port 8).
5. Because there are VLAN 100 ports on switch B (ports 4 and 5), the data frame is forwarded to those ports. As with switch A, the data frame is not delivered to VLAN 200.

If there were no VLAN 100 ports on switch B, the switch would not forward the data frame and it would stop there.

6. The switch removes the VLAN 100 ID tag before it forwards the data frame to an end destination.

The sending and receiving computers are not aware of any VLAN tagging on the data frames that are being transmitted. When any computer receives that data frame, it appears as a normal data frame.

## VLAN layer-3 routing

Routers are layer-3 devices. Layer 3 refers to the third layer of the OSI networking model, the Network layer. FortiGate units in NAT mode act as layer-3 devices. As with layer 2, FortiGate units acting as layer-3 devices are 802.1Q-compliant.

The main difference between layer-2 and layer-3 devices is how they process VLAN tags. Layer-2 switches just add, read and remove the tags. They do not alter the tags or do any other high-level actions. Layer-3 routers not only add, read and remove tags but also analyze the data frame and its contents. This analysis allows layer-3 routers to change the VLAN tag if it is appropriate and send the data frame out on a different VLAN.

In a layer-3 environment, the 802.1Q-compliant router receives the data frame and assigns a VLAN ID. The router then forwards the data frame to other members of the same VLAN broadcast domain. The broadcast domain can include local ports, layer-2 devices and layer-3 devices such as routers and firewalls. When a layer-3 device receives the data frame, the device removes the VLAN tag and examines its contents to decide what to do with the data frame. The layer-3 device considers:

- source and destination addresses
- protocol
- port number.

The data frame may be forwarded to another VLAN, sent to a regular non-VLAN-tagged network or just forwarded to the same VLAN as a layer-2 switch would do. Or, the data frame may be discarded if the proper security policy has been configured to do so.

### Layer-3 VLAN example

In this example, switch A is connected to the Branch Office subnet, the same as subnet 1 in the layer-2 example. In the Main Office subnet, VLAN 300 is on port 5 of switch B. The FortiGate unit is connected to switch B on port 1 and the trunk link connects the FortiGate unit's port 3 to switch A. The other ports on switch B are unassigned.

This example explains how traffic can change VLANs originating on VLAN 100 and arriving at a destination on VLAN 300. Layer-2 switches alone cannot accomplish this, but a layer-3 router can.

1. The VLAN 100 computer at the Branch Office sends the data frame to switch A, where the VLAN 100 tag is added.

2. Switch A forwards the tagged data frame to the FortiGate unit over the 802.1Q trunk link, and to the VLAN 100 interfaces on Switch A.

Up to this point everything is the same as in the layer-2 example.

3. The FortiGate unit removes the VLAN 100 tag, and inspects the content of the data frame. The FortiGate unit uses the content to select the correct security policy and routing options.
4. The FortiGate unit's security policy allows the data frame to go to VLAN 300 in this example. The data frame will be sent to all VLAN 300 interfaces, but in the example there is only port 1

on the FortiGate unit. Before the data frame leaves, the FortiGate unit adds the VLAN ID 300 tag to the data frame.

This is the step that layer 2 cannot do. Only layer 3 can retag a data frame as a different VLAN.

5. Switch B receives the data frame, and removes the VLAN ID 300 tag, because this is the last hop, and forwards the data frame to the computer on port 5.

In this example, a data frame arrived at the FortiGate unit tagged as VLAN 100. After checking its content, the FortiGate unit retagged the data frame for VLAN 300. It is this change from

VLAN 100 to VLAN 300 that requires a layer-3 routing device, in this case the FortiGate unit. Layer-2 switches cannot perform this change.

## VLANs in NAT mode

In NAT mode the FortiGate unit functions as a layer-3 device. In this mode, the FortiGate unit controls the flow of packets between VLANs, but can also remove VLAN tags from incoming VLAN packets. The FortiGate unit can also forward untagged packets to other networks, such as the Internet.

In NAT mode, the FortiGate unit supports VLAN trunk links with IEEE 802.1Q-compliant switches, or routers. The trunk link transports VLAN-tagged packets between physical subnets or networks. When you add VLAN sub-interfaces to the FortiGate unit physical interfaces, the VLANs have IDs that match the VLAN IDs of packets on the trunk link. The FortiGate unit directs packets with VLAN IDs to sub-interfaces with matching IDs.

You can define VLAN sub-interfaces on all FortiGate physical interfaces. However, if multiple virtual domains are configured on the FortiGate unit, you will have access to only the physical interfaces on your virtual domain. The FortiGate unit can tag packets leaving on a VLAN subinterface. It can also remove VLAN tags from incoming packets and add a different VLAN tag to outgoing packets.

Normally in VLAN configurations, the FortiGate unit's internal interface is connected to a VLAN trunk, and the external interface connects to an Internet router that is not configured for VLANs. In this configuration the FortiGate unit can apply different policies for traffic on each VLAN interface connected to the internal interface, which results in less network traffic and better security.

## Adding VLAN subinterfaces

A VLAN subinterface, also called a VLAN, is a virtual interface on a physical interface. The subinterface allows routing of VLAN tagged packets using that physical interface, but it is separate from any other traffic on the physical interface.

Adding a VLAN subinterface includes configuring:

- [Physical interface](#)
- [IP address and netmask](#)
- [VLAN ID](#)
- [VDOM](#)

### Physical interface

The term VLAN subinterface correctly implies the VLAN interface is not a complete interface by itself. You add a VLAN subinterface to the physical interface that receives VLAN-tagged packets. The physical interface can belong to a different VDOM than the VLAN, but it must be connected to a network router that is configured for this VLAN. Without that router, the VLAN will not be connected to the network, and VLAN traffic will not be able to access this interface. The traffic on the VLAN is separate from any other traffic on the physical interface.

When you are working with interfaces on your FortiGate unit, use the *Column Settings* on the Interface display to make sure the information you need is displayed. When working with VLANs, it is useful to position the *VLAN ID* column close to the IP address. If you are working with VDOMs, including the *Virtual Domain* column as well will help you troubleshoot problems more quickly.

To view the Interface display, go to *System > Network > Interface*.

## IP address and netmask

FortiGate unit interfaces cannot have overlapping IP addresses. The IP addresses of all interfaces must be on different subnets. This rule applies to both physical interfaces and to virtual interfaces such as VLAN subinterfaces. Each VLAN subinterface must be configured with its own IP address and netmask pair. This rule helps prevent a broadcast storm or other similar network problems.

If you are unable to change your existing configurations to prevent IP overlap, enter the CLI command `config system global and set ip-overlap enable` to allow IP address overlap. If you enter this command, multiple VLAN interfaces can have an IP address that is part of a subnet used by another interface. This command is recommended for advanced users only.

## VLAN ID

The VLAN ID is part of the VLAN tag added to the packets by VLAN switches and routers. The VLAN ID is a number between 1 and 4094 that allow groups of IP addresses with the same VLAN ID to be associated together. VLAN ID 0 is used only for high priority frames, and 4095 is reserved.

All devices along a route must support the VLAN ID of the traffic along that route. Otherwise, the traffic will be discarded before reaching its destination. For example, if your computer is part of VLAN\_100 and a co-worker on a different floor of your building is also on the same VLAN\_100, you can communicate with each other over VLAN\_100, only if all the switches and routers support VLANs and are configured to pass along VLAN\_100 traffic properly. Otherwise, any traffic you send your co-worker will be blocked or not delivered.

## VDOM

If VDOMs are enabled, each VLAN subinterface must belong to a VDOM. This rule also applies for physical interfaces.

Interface-related CLI commands require a VDOM to be specified, regardless of whether the FortiGate unit has VDOMs enabled.

VLAN subinterfaces on separate VDOMs cannot communicate directly with each other. In this situation, the VLAN traffic must exit the FortiGate unit and re-enter the unit again, passing through firewalls in both directions. This situation is the same for physical interfaces.

A VLAN subinterface can belong to a different VDOM than the physical interface it is part of. This is because the traffic on the VLAN is handled separately from the other traffic on that interface. This is one of the main strengths of VLANs.

The following procedure will add a VLAN subinterface called `VLAN_100` to the FortiGate internal interface with a VLAN ID of 100. It will have an IP address and netmask of `172.100.1.1/255.255.255.0`, and allow HTTPS, PING, and Telnet administrative access. Note that in the CLI, you must enter “`set type vlan`” before setting the `vlanid`, and that the `allowaccess` protocols are lower case.

### To add a VLAN subinterface in NAT mode - web-based manager

1. If *Current VDOM* appears at the bottom left of the screen, select *Global* from the list of VDOMs.
2. Go to *System > Network > Interface*.

3. Select *Create New* to add a VLAN subinterface.
4. Enter the following:

<b>VLAN Name</b>	VLAN_100
<b>Type</b>	VLAN
<b>Interface</b>	internal
<b>VLAN ID</b>	100
<b>Addressing Mod</b>	Manual
<b>IP/Netmask</b>	172.100.1.1/255.255.255.0
<b>Administrative Access</b>	HTTPS, PING, TELNET

5. Select *OK*.

To view the new VLAN subinterface, select the expand arrow next to the parent physical interface (the internal interface). This will expand the display to show all VLAN subinterfaces on this physical interface. If there is no expand arrow displayed, there are no subinterfaces configured on that physical interface.

For each VLAN, the list displays the name of the VLAN, and, depending on column settings, its IP address, the Administrative access you selected for it, the VLAN ID number, and which VDOM it belongs to if VDOMs are enabled.

#### To add a VLAN subinterface in NAT mode - CLI

```
config system interface
  edit VLAN_100
    set interface internal
    set type vlan
    set vlanid 100
    set ip 172.100.1.1 255.255.255.0
    set allowaccess https ping telnet
  end
```

## Configuring security policies and routing

Once you have created a VLAN subinterface on the FortiGate unit, you need to configure security policies and routing for that VLAN. Without these, the FortiGate unit will not pass VLAN traffic to its intended destination. Security policies direct traffic through the FortiGate unit between interfaces. Routing directs traffic across the network.

### Configuring security policies

Security policies permit communication between the FortiGate unit's network interfaces based on source and destination IP addresses. Interfaces that communicate with the VLAN interface need security policies to permit traffic to pass between them and the VLAN interface.

Each VLAN needs a security policy for each of the following connections the VLAN will be using:

- from this VLAN to an external network
- from an external network to this VLAN
- from this VLAN to another VLAN in the same virtual domain on the FortiGate unit
- from another VLAN to this VLAN in the same virtual domain on the FortiGate unit.

The packets on each VLAN are subject to antivirus scans and other UTM measures as they pass through the FortiGate unit.

## Configuring routing

As a minimum, you need to configure a default static route to a gateway with access to an external network for outbound packets. In more complex cases, you will have to configure different static or dynamic routes based on packet source and destination addresses.

As with firewalls, you need to configure routes for VLAN traffic. VLANs need routing and a gateway configured to send and receive packets outside their local subnet just as physical interfaces do. The type of routing you configure, static or dynamic, will depend on the routing used by the subnet and interfaces you are connecting to. Dynamic routing can be routing information protocol (RIP), border gateway protocol (BGP), open shortest path first (OSPF), or multicast.

If you enable SSH, PING, Telnet, HTTPS and HTTP on the VLAN, you can use those protocols to troubleshoot your routing and test that it is properly configured. Enabling logging on the interfaces and using CLI diagnose commands such as `diagnose sniff packet <interface_name>` can also help locate any possible configuration or hardware issues.

## Example VLAN configuration in NAT mode

In this example two different internal VLAN networks share one interface on the FortiGate unit, and share the connection to the Internet. This example shows that two networks can have separate traffic streams while sharing a single interface. This configuration could apply to two departments in a single company, or to different companies.

There are two different internal network VLANs in this example. VLAN\_100 is on the 10.1.1.0/255.255.255.0 subnet, and VLAN\_200 is on the 10.1.2.0/255.255.255.0 subnet. These VLANs are connected to the VLAN switch, such as a Cisco 2950 Catalyst switch.

The FortiGate internal interface connects to the VLAN switch through an 802.1Q trunk. The internal interface has an IP address of 192.168.110.126 and is configured with two VLAN subinterfaces (VLAN\_100 and VLAN\_200). The external interface has an IP address of 172.16.21.2 and connects to the Internet. The external interface has no VLAN subinterfaces.

**Figure 240:**FortiGate unit with VLANs in NAT mode

When the VLAN switch receives packets from VLAN\_100 and VLAN\_200, it applies VLAN ID tags and forwards the packets of each VLAN both to local ports and to the FortiGate unit across the trunk link. The FortiGate unit has policies that allow traffic to flow between the VLANs, and from the VLANs to the external network.

This section describes how to configure a FortiGate unit and a Cisco Catalyst 2950 switch for this example network topology. The Cisco configuration commands used in this section are IOS commands.

It is assumed that both the FortiGate unit and the Cisco 2950 switch are installed and connected and that basic configuration has been completed. On the switch, you will need to be able to access the CLI to enter commands. Refer to the manual for your FortiGate model as well as the manual for the switch you select for more information.

It is also assumed that no VDOMs are enabled.

## General configuration steps

The following steps provide an overview of configuring and testing the hardware used in this example. For best results in this configuration, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Configure the FortiGate unit
  - Configure the external interface
  - Add two VLAN subinterfaces to the internal network interface
  - Add firewall addresses and address ranges for the internal and external networks
  - Add security policies to allow:
    - the VLAN networks to access each other
    - the VLAN networks to access the external network.
2. Configure the VLAN switch

## Configure the FortiGate unit

Configuring the FortiGate unit includes:

- [Configure the external interface](#)
- [Add VLAN subinterfaces](#)
- [Add the firewall addresses](#)
- [Add the security policies](#)

### Configure the external interface

The FortiGate unit's external interface will provide access to the Internet for all internal networks, including the two VLANs.

#### To configure the external interface - web-based manager

1. Go to *System > Network > Interface*.
2. Select *Edit* for the external interface.
3. Enter the following information and select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Network Mask</b>	172.16.21.2/255.255.255.0

#### To configure the external interface - CLI

```
config system interface
    edit external
        set mode static
        set ip 172.16.21.2 255.255.255.0
    end
```

### Add VLAN subinterfaces

This step creates the VLANs on the FortiGate unit internal physical interface. The IP address of the internal interface does not matter to us, as long as it does not overlap with the subnets of the VLAN subinterfaces we are configuring on it.

The rest of this example shows how to configure the VLAN behavior on the FortiGate unit, configure the switches to direct VLAN traffic the same as the FortiGate unit, and test that the configuration is correct.

Adding VLAN subinterfaces can be completed through the web-based manager, or the CLI.

#### To add VLAN subinterfaces - web-based manager

1. Go to *System > Network > Interface*.
2. Select *Create New*.
3. Enter the following information and select *OK*:

<b>Name</b>	VLAN_100
<b>Interface</b>	internal
<b>VLAN ID</b>	100
<b>Addressing mode</b>	Manual

<b>IP/Network Mask</b>	10.1.1.1/255.255.255.0
<b>Administrative Access</b>	HTTPS, PING, TELNET

4. Select *Create New*.
5. Enter the following information and select *OK*:

<b>Name</b>	VLAN_200
<b>Interface</b>	internal
<b>VLAN ID</b>	200
<b>Addressing mode</b>	Manual
<b>IP/Network Mask</b>	10.1.2.1/255.255.255.0
<b>Administrative Access</b>	HTTPS, PING, TELNET

#### To add VLAN subinterfaces - CLI

```
config system interface
  edit VLAN_100
    set vdom root
    set interface internal
    set type vlan
    set vlanid 100
    set mode static
    set ip 10.1.1.1 255.255.255.0
    set allowaccess https ping telnet
  next
  edit VLAN_200
    set vdom root
    set interface internal
    set type vlan
    set vlanid 200
    set mode static
    set ip 10.1.2.1 255.255.255.0
    set allowaccess https ping telnet
end
```

#### Add the firewall addresses

You need to define the addresses of the VLAN subnets for use in security policies. The FortiGate unit provides one default address, “all”, that you can use when a security policy applies to all addresses as a source or destination of a packet. However, using “all” is less secure and should be avoided when possible.

In this example, the “\_Net” part of the address name indicates a range of addresses instead of a unique address. When choosing firewall address names, use informative and unique names.

#### To add the firewall addresses - web-based manager

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New*.

3. Enter the following information and select *OK*:

<b>Name</b>	VLAN_100_Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	10.1.1.0/255.255.255.0

4. Select *Create New*.

5. Enter the following information and select *OK*:

<b>Name</b>	VLAN_200_Net
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	10.1.2.0/255.255.255.0

#### To add the firewall addresses - CLI

```
config firewall address
  edit VLAN_100_Net
    set type ipmask
    set subnet 10.1.1.0 255.255.255.0
  next
  edit VLAN_200_Net
    set type ipmask
    set subnet 10.1.2.0 255.255.255.0
end
```

#### Add the security policies

Once you have assigned addresses to the VLANs, you need to configure security policies for them to allow valid packets to pass from one VLAN to another and to the Internet.

You can customize the Security Policy display by including some or all columns, and customize the column order onscreen. Due to this feature, security policy screenshots may not appear the same as on your screen.

If you do not want to allow all services on a VLAN, you can create a security policy for each service you want to allow. This example allows all services.

#### To add the security policies - web-based manager

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
3. Enter the following information and select *OK*:

<b>Incoming Interface</b>	VLAN_100
<b>Source Address</b>	VLAN_100_Net
<b>Outgoing Interface</b>	VLAN_200
<b>Destination Address</b>	VLAN_200_Net

<b>Schedule</b>	Always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Enable

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
6. Enter the following information and select *OK*:

<b>Incoming Interface</b>	VLAN_200
<b>Source Address</b>	VLAN_200_Net
<b>Outgoing Interface</b>	VLAN_100
<b>Destination Address</b>	VLAN_100_Net
<b>Schedule</b>	Always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Enable

7. Select *Create New*.
8. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
9. Enter the following information and select *OK*:

<b>Incoming Interface</b>	VLAN_100
<b>Source Address</b>	VLAN_100_Net
<b>Outgoing Interface</b>	external
<b>Destination Address</b>	all
<b>Schedule</b>	Always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Enable

10. Select *Create New*.
11. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
12. Enter the following information and select *OK*:

<b>Incoming Interface</b>	VLAN_200
<b>Source Address</b>	VLAN_200_Net

<b>Outgoing Interface</b>	external
<b>Destination Address</b>	all
<b>Schedule</b>	Always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Enable

### To add the security policies - CLI

```
config firewall policy
  edit 1
    set srcintf VLAN_100
    set srcaddr VLAN_100_Net
    set dstintf VLAN_200
    set dstaddr VLAN_200_Net
    set schedule always
    set service ALL
    set action accept
    set nat enable
    set status enable
  next
  edit 2
    set srcintf VLAN_200
    set srcaddr VLAN_200_Net
    set dstintf VLAN_100
    set dstaddr VLAN_100_Net
    set schedule always
    set service ALL
    set action accept
    set nat enable
    set status enable
  next
  edit 3
    set srcintf VLAN_100
    set srcaddr VLAN_100_Net
    set dstintf external
    set dstaddr all
    set schedule always
    set service ALL
    set action accept
    set nat enable
    set status enable
  next
  edit 4
    set srcintf VLAN_200
    set srcaddr VLAN_200_Net
```

```
set dstintf external
set dstaddr all
set schedule always
set service ALL
set action accept
set nat enable
set status enable
end
```

## Configure the VLAN switch

On the Cisco Catalyst 2950 Catalyst VLAN switch, you need to define VLANs 100 and 200 in the VLAN database, and then add a configuration file to define the VLAN subinterfaces and the 802.1Q trunk interface.

One method to configure a Cisco switch is to connect over a serial connection to the console port on the switch, and enter the commands at the CLI. Another method is to designate one interface on the switch as the management interface and use a web browser to connect to the switch's graphical interface. For details on connecting and configuring your Cisco switch, refer to the installation and configuration manuals for the switch.

The switch used in this example is a Cisco Catalyst 2950 switch. The commands used are IOS commands. Refer to the switch manual for help with these commands.

### To configure the VLAN subinterfaces and the trunk interfaces

Add this file to the Cisco switch:

```
!
interface FastEthernet0/3
switchport access vlan 100
!
interface FastEthernet0/9
switchport access vlan 200
!
interface FastEthernet0/24
switchport trunk encapsulation dot1q
switchport mode trunk
!
```

The switch has the configuration:

<b>Port 0/3</b>	VLAN ID 100
<b>Port 0/9</b>	VLAN ID 200
<b>Port 0/24</b>	802.1Q trunk

To complete the setup, configure devices on VLAN\_100 and VLAN\_200 with default gateways. The default gateway for VLAN\_100 is the FortiGate VLAN\_100 subinterface. The default gateway for VLAN\_200 is the FortiGate VLAN\_200 subinterface.

## Test the configuration

Use diagnostic commands, such as `tracert`, to test traffic routed through the FortiGate unit and the Cisco switch.

### Testing traffic from VLAN\_100 to VLAN\_200

In this example, a route is traced between the two internal networks. The route target is a host on VLAN\_200.

Access a command prompt on a Windows computer on the VLAN\_100 network, and enter the following command:

```
C:\>tracert 10.1.2.2
Tracing route to 10.1.2.2 over a maximum of 30 hops:
  1  <10 ms  <10 ms  <10 ms  10.1.1.1
  2  <10 ms  <10 ms  <10 ms  10.1.2.2
Trace complete.
```

### Testing traffic from VLAN\_200 to the external network

In this example, a route is traced from an internal network to the external network. The route target is the external network interface of the FortiGate-800 unit.

From VLAN\_200, access a command prompt and enter this command:

```
C:\>tracert 172.16.21.2
Tracing route to 172.16.21.2 over a maximum of 30 hops:
  1  <10 ms  <10 ms  <10 ms  10.1.2.1
  2  <10 ms  <10 ms  <10 ms  172.16.21.2
Trace complete.
```

## VLANs in transparent mode

In transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering and intrusion protection to traffic. There are some limitations in transparent mode in that you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

### VLANs and transparent mode

You can insert the FortiGate unit operating in transparent mode into the VLAN trunk without making changes to your network. In a typical configuration, the FortiGate unit internal interface accepts VLAN packets on a VLAN trunk from a VLAN switch or router connected to internal network VLANs. The FortiGate external interface forwards VLAN-tagged packets through another VLAN trunk to an external VLAN switch or router and on to external networks such as the Internet. You can configure the unit to apply different policies for traffic on each VLAN in the trunk.

To pass VLAN traffic through the FortiGate unit, you add two VLAN subinterfaces with the same VLAN ID, one to the internal interface and the other to the external interface. You then create a security policy to permit packets to flow from the internal VLAN interface to the external VLAN interface. If required, you create another security policy to permit packets to flow from the external VLAN interface to the internal VLAN interface. Typically in transparent mode, you do not permit packets to move between different VLANs. Network protection features, such as

spam filtering, web filtering and anti-virus scanning, are applied through the UTM profiles specified in each security policy, enabling very detailed control over traffic.

When the FortiGate unit receives a VLAN-tagged packet at a physical interface, it directs the packet to the VLAN subinterface with the matching VLAN ID. The VLAN tag is removed from the packet, and the FortiGate unit then applies security policies using the same method it uses for non-VLAN packets. If the packet exits the FortiGate unit through a VLAN subinterface, the VLAN ID for that subinterface is added to the packet and the packet is sent to the corresponding physical interface. For a configuration example, see [“Example of VLANs in transparent mode” on page 1544](#).

There are two essential steps to configure your FortiGate unit to work with VLANs in transparent mode:

- [Add VLAN subinterfaces](#)
- [Create security policies](#)

You can also configure the protection profiles that manage antivirus scanning, web filtering and spam filtering. For more information on UTM profiles, see [“Unified Threat Management for FortiOS 5.0” on page 2018](#).

### Add VLAN subinterfaces

The VLAN ID of each VLAN subinterface must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch. The VLAN ID can be any number between 1 and 4094, with 0 being used only for high priority frames and 4095 being reserved. You add VLAN subinterfaces to the physical interface that receives VLAN-tagged packets.

For this example, we are creating a VLAN called `internal_v225` on the internal interface, with a VLAN ID of 225. Administrative access is enabled for HTTPS and SSH. VDOMs are not enabled.

#### To add VLAN subinterfaces in transparent mode - web-based manager

1. Go to *System > Network > Interface*.
2. Select *Create New*.
3. Enter the following information and select *OK*.

<b>Name</b>	internal_v225
<b>Type</b>	VLAN
<b>Interface</b>	internal
<b>VLAN ID</b>	225
<b>Administrative Access</b>	Enable HTTPS, and SSH. These are very secure access methods.
<b>Comments</b>	VLAN 225 on internal interface

The FortiGate unit adds the new subinterface to the interface that you selected.

Repeat steps 2 and 3 to add additional VLANs. You will need to change the *VLAN ID*, *Name*, and possibly *Interface* when adding additional VLANs.

### To add VLAN subinterfaces in transparent mode - CLI

```
config system interface
  edit internal_v225
    set interface internal
    set vlanid 225
    set allowaccess HTTPS SSH
    set description "VLAN 225 on internal interface"
    set vdom root
  end
```

### Create security policies

In transparent mode, the FortiGate unit performs antivirus and antispam scanning on each VLAN's packets as they pass through the unit. You need security policies to permit packets to pass from the VLAN interface where they enter the unit to the VLAN interface where they exit the unit. If there are no security policies configured, no packets will be allowed to pass from one interface to another.

### To add security policies for VLAN subinterfaces - web based manager

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New* to add firewall addresses that match the source and destination IP addresses of VLAN packets.
3. Go to *Policy > Policy > Policy* and select *Create New*.
4. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
5. From the *Incoming Interface/Zone* list, select the VLAN interface where packets enter the unit.
6. From the *Outgoing Interface/Zone* list, select the VLAN interface where packets exit the unit.
7. Select the *Source* and *Destination Address* names that you added in step 2.
8. Select *OK*.

### To add security policies for VLAN subinterfaces - CLI

```
config firewall address
  edit incoming_VLAN_address
    set associated-interface <incoming_VLAN_interface>
    set type ipmask
    set subnet <IPv4_address_mask>
  next
  edit outgoing_VLAN_address
    set associated-interface <outgoing_VLAN_interface>
    set type ipmask
    set subnet <IPv4_address_mask>
  next
end
config firewall policy
  edit <unused_policy_number>
    set srcintf <incoming_VLAN_interface>
    set srcaddr incoming_VLAN_address
    set destintf <outgoing_VLAN_interface>
```

```

set destaddr outgoing_VLAN_address
set service <protocol_to_allow_on_VLAN>
set action ACCEPT
next
end

```

## Example of VLANs in transparent mode

In this example, the FortiGate unit is operating in transparent mode and is configured with two VLANs: one with an ID of 100 and the other with ID 200. The internal and external physical interfaces each have two VLAN subinterfaces, one for VLAN\_100 and one for VLAN\_200.

The IP range for the internal VLAN\_100 network is 10.100.0.0/255.255.0.0, and for the internal VLAN\_200 network is 10.200.0.0/255.255.0.0.

The internal networks are connected to a Cisco 2950 VLAN switch, which combines traffic from the two VLANs onto one the FortiGate unit internal interface. The VLAN traffic leaves the FortiGate unit on the external network interface, goes on to the VLAN switch, and on to the Internet. When the FortiGate unit receives a tagged packet, it directs it from the incoming VLAN subinterface to the outgoing VLAN subinterface for that VLAN.

This section describes how to configure a FortiGate-800 unit, Cisco switch, and Cisco router in the network topology shown in [Figure 180](#).

**Figure 241:** VLAN transparent network topology

## General configuration steps

The following steps summarize the configuration for this example. For best results, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Configure the FortiGate unit which includes
  - Adding VLAN subinterfaces
  - Adding the security policies
2. Configure the Cisco switch and router

## Configure the FortiGate unit

The FortiGate unit must be configured with the VLAN subinterfaces and the proper security policies to enable traffic to flow through the FortiGate unit.

### Add VLAN subinterfaces

For each VLAN, you need to create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID.

#### To add VLAN subinterfaces - web-based manager

1. Go to *System > Network > Interface*.
2. Select *Create New*.
3. Enter the following information and select *OK*:

<b>Name</b>	VLAN_100_int
<b>Interface</b>	internal
<b>VLAN ID</b>	100

4. Select *Create New*.
5. Enter the following information and select *OK*:

<b>Name</b>	VLAN_100_ext
<b>Interface</b>	external
<b>VLAN ID</b>	100

6. Select *Create New*.
7. Enter the following information and select *OK*:

<b>Name</b>	VLAN_200_int
<b>Interface</b>	internal
<b>VLAN ID</b>	200

8. Select *Create New*.
9. Enter the following information and select *OK*:

<b>Name</b>	VLAN_200_ext
<b>Interface</b>	external
<b>VLAN ID</b>	200

## To add VLAN subinterfaces - CLI

```
config system interface
  edit VLAN_100_int
    set status down
    set type vlan
    set interface internal
    set vlanid 100
  next
  edit VLAN_100_ext
    set status down
    set type vlan
    set interface external
    set vlanid 100
  next
  edit VLAN_200_int
    set status down
    set type vlan
    set interface internal
    set vlanid 200
  next
  edit VLAN_200_ext
    set status down
    set type vlan
    set interface external
    set vlanid 200
end
```

## Add the security policies

Security policies allow packets to travel between the VLAN\_100\_int interface and the VLAN\_100\_ext interface. Two policies are required; one for each direction of traffic. The same is required between the VLAN\_200\_int interface and the VLAN\_200\_ext interface, for a total of four required security policies.

### To add the security policies - web-based manager

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
3. Enter the following information and select *OK*:

<b>Incoming Interface</b>	VLAN_100_int
<b>Source Address</b>	all
<b>Outgoing Interface</b>	VLAN_100_ext
<b>Destination Address</b>	all
<b>Schedule</b>	Always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
6. Enter the following information and select *OK*:

<b>Incoming Interface</b>	VLAN_100_ext
<b>Source Address</b>	all
<b>Outgoing Interface</b>	VLAN_100_int
<b>Destination Address</b>	all
<b>Schedule</b>	Always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT

7. Go to *Policy > Policy > Policy* and select *Create New*.
8. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
9. Enter the following information and select *OK*:

<b>Incoming Interface</b>	VLAN_200_int
<b>Source Address</b>	all
<b>Outgoing Interface</b>	VLAN_200_ext
<b>Destination Address</b>	all
<b>Schedule</b>	Always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Enable

10. Select *Create New*.
11. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
12. Enter the following information and select *OK*:

<b>Incoming Interface</b>	VLAN_200_ext
<b>Source Address</b>	all
<b>Outgoing Interface</b>	VLAN_200_int
<b>Destination Address</b>	all
<b>Schedule</b>	Always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT

### To add the security policies - CLI

```
config firewall policy
edit 1
    set srcintf VLAN_100_int
    set srcaddr all
    set dstintf VLAN_100_ext
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
edit 2
    set srcintf VLAN_100_ext
    set srcaddr all
    set dstintf VLAN_100_int
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
edit 3
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
next
edit 4
    set srcintf VLAN_200_ext
    set srcaddr all
    set dstintf VLAN_200_int
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
end
```

## Configure the Cisco switch and router

This example includes configuration for the Cisco Catalyst 2900 ethernet switch, and for the Cisco Multiservice 2620 ethernet router. If you have access to a different VLAN enabled switch or VLAN router you can use them instead, however their configuration is not included in this document.

### Configure the Cisco switch

On the VLAN switch, you need to define VLAN\_100 and VLAN\_200 in the VLAN database and then add a configuration file to define the VLAN subinterfaces and the 802.1Q trunk interface.

Add this file to the Cisco switch:

```
interface FastEthernet0/3
  switchport access vlan 100
!
interface FastEthernet0/9
  switchport access vlan 200
!
interface FastEthernet0/24
  switchport trunk encapsulation dot1q
  switchport mode trunk
!
```

The switch has the following configuration:

<b>Port 0/3</b>	VLAN ID 100
<b>Port 0/9</b>	VLAN ID 200
<b>Port 0/24</b>	802.1Q trunk

### Configure the Cisco router

You need to add a configuration file to the Cisco Multiservice 2620 ethernet router. The file defines the VLAN subinterfaces and the 802.1Q trunk interface on the router. The 802.1Q trunk is the physical interface on the router.

The IP address for each VLAN on the router is the gateway for that VLAN. For example, all devices on the internal VLAN\_100 network will have 10.100.0.1 as their gateway.

Add this file to the Cisco router:

```
!
interface FastEthernet0/0
!
interface FastEthernet0/0.1
  encapsulation dot1Q 100
  ip address 10.100.0.1 255.255.255.0
!
interface FastEthernet0/0.2
  encapsulation dot1Q 200
  ip address 10.200.0.1 255.255.255.0
!
```

The router has the following configuration:

<b>Port 0/0.1</b>	VLAN ID 100
<b>Port 0/0.2</b>	VLAN ID 200
<b>Port 0/0</b>	802.1Q trunk

## Test the configuration

Use diagnostic network commands such as traceroute (`tracert`) and ping to test traffic routed through the network.

### Testing traffic from VLAN\_100 to VLAN\_200

In this example, a route is traced between the two internal networks. The route target is a host on VLAN\_200. The Windows traceroute command `tracert` is used.

From VLAN\_100, access a Windows command prompt and enter this command:

```
C:\>tracert 10.1.2.2
Tracing route to 10.1.2.2 over a maximum of 30 hops:
  1  <10 ms  <10 ms  <10 ms  10.1.1.1
  2  <10 ms  <10 ms  <10 ms  10.1.2.2
Trace complete.
```

## Troubleshooting VLAN issues

Several problems can occur with your VLANs. Since VLANs are interfaces with IP addresses, they behave as interfaces and can have similar problems that you can diagnose with tools such as ping, traceroute, packet sniffing, and diag debug.

### Asymmetric routing

You might discover unexpectedly that hosts on some networks are unable to reach certain other networks. This occurs when request and response packets follow different paths. If the FortiGate unit recognizes the response packets, but not the requests, it blocks the packets as invalid. Also, if the FortiGate unit recognizes the same packets repeated on multiple interfaces, it blocks the session as a potential attack.

This is asymmetric routing. By default, the FortiGate unit blocks packets or drops the session when this happens. You can configure the FortiGate unit to permit asymmetric routing by using the following CLI commands:

```
config vdom
  edit <vdom_name>
    config system settings
      set asymroute enable
    end
  end
```

If VDOMs are enabled, this command is per VDOM. You must set it for each VDOM that has the problem. If this solves your blocked traffic issue, you know that asymmetric routing is the cause. But allowing asymmetric routing is not the best solution, because it reduces the security of your network.

For a long-term solution, it is better to change your routing configuration or change how your FortiGate unit connects to your network. The [Asymmetric Routing and Other FortiGate Layer-2](#)

[Installation Issues](#) technical note provides detailed examples of asymmetric routing situations and possible solutions.

If you enable asymmetric routing, antivirus and intrusion prevention systems will not be effective. Your FortiGate unit will be unaware of connections and treat each packet individually. It will become a stateless firewall.

## Layer-2 and Arp traffic

By default, FortiGate units do not pass layer-2 traffic. If there are layer-2 protocols such as IPX, PPTP or L2TP in use on your network, you need to configure your FortiGate unit interfaces to pass these protocols without blocking. Another type of layer-2 traffic is ARP traffic. For more information on ARP traffic, see [“ARP traffic” on page 1551](#).

You can allow these layer-2 protocols using the CLI command:

```
config vdom
  edit <vdom_name>
    config system interface
      edit <name_str>
        set l2forward enable
      end
    end
  end
```

where <name\_str> is the name of an interface.

If VDOMs are enabled, this command is per VDOM. You must set it for each VDOM that has the problem. If you enable layer-2 traffic, you may experience a problem if packets are allowed to repeatedly loop through the network. This repeated looping, very similar to a broadcast storm, occurs when you have more than one layer-2 path to a destination. Traffic may overflow and bring your network to a halt. You can break the loop by enabling Spanning Tree Protocol (STP) on your network's switches and routers. For more information, see [“STP forwarding” on page 1262](#).

## ARP traffic

Address Resolution Protocol (ARP) packets are vital to communication on a network, and ARP support is enabled on FortiGate unit interfaces by default. Normally you want ARP packets to pass through the FortiGate unit, especially if it is sitting between a client and a server or between a client and a router.

ARP traffic can cause problems, especially in transparent mode where ARP packets arriving on one interface are sent to all other interfaces including VLAN subinterfaces. Some layer-2 switches become unstable when they detect the same MAC address originating on more than one switch interface or from more than one VLAN. This instability can occur if the layer-2 switch does not maintain separate MAC address tables for each VLAN. Unstable switches may reset and cause network traffic to slow down considerably.

The default ARP timeout value is 5 minutes (300 seconds). This timeout is not configurable.

Usually ARP entries are removed after 5 minutes. However, some conditions can cause ARP entries to remain for a longer time. Enter the `get system arp` CLI command to view the entries in the ARP list.

## Multiple VDOMs solution

By default, physical interfaces are in the root domain. If you do not configure any of your VLANs in the root VDOM, it will not matter how many interfaces are in the root VDOM.

The multiple VDOMs solution is to configure multiple VDOMs on the FortiGate unit, one for each VLAN. In this solution, you configure one inbound and one outbound VLAN interface in each VDOM. ARP packets are not forwarded between VDOMs. This configuration limits the VLANs in a VDOM and correspondingly reduces the administration needed per VDOM.

As a result of this configuration, the switches do not receive multiple ARP packets with duplicate MACs. Instead, the switches receive ARP packets with different VLAN IDs and different MACs. Your switches are stable.

However, you should **not** use the multiple VDOMs solution under any of the following conditions:

- you have more VLANs than licensed VDOMs
- you do not have enough physical interfaces

Instead, use one of two possible solutions, depending on which operation mode you are using:

- In NAT mode, you can use the `vlan forward` CLI command.
- In transparent mode, you can use the `forward-domain` CLI command. But you still need to be careful in some rare configurations.

## Vlanforward solution

If you are using NAT mode, the solution is to use the `vlanforward` CLI command for the interface in question. By default, this command is enabled and will forward VLAN traffic to all VLANs on this interface. When disabled, each VLAN on this physical interface can send traffic only to the same VLAN. There is no cross-talk between VLANs, and ARP packets are forced to take one path along the network which prevents the multiple paths problem.

In the following example, `vlanforward` is disabled on port1. All VLANs configured on port1 will be separate and will not forward any traffic to each other.

```
config system interface
    edit port1
        set vlanforward disable
    end
```

## Forward-domain solution

If you are using transparent mode, the solution is to use the `forward-domain` CLI command. This command tags VLAN traffic as belonging to a particular collision group, and only VLANs tagged as part of that collision group receive that traffic. It is like an additional set of VLANs. By default, all interfaces and VLANs are part of forward-domain collision group 0. The many benefits of this solution include reduced administration, the need for fewer physical interfaces, and the availability of more flexible network solutions.

In the following example, forward-domain collision group 340 includes VLAN 340 traffic on port1 and untagged traffic on port 2. Forward-domain collision group 341 includes VLAN 341 traffic on port 1 and untagged traffic on port 3. All other interfaces are part of forward-domain collision group 0 by default. This configuration separates VLANs 340 and 341 from each other on port 1, and prevents the ARP packet problems from before.

Use these CLI commands:

```
config system interface
    edit port1
```

```

next
edit port2
    set forward_domain 340
next
edit port3
    set forward_domain 341
next
edit port1-340
    set forward_domain 340
    set interface port1
    set vlanid 340
next
edit port1-341
    set forward_domain 341
    set interface port1
    set vlanid 341
end

```

You may experience connection issues with layer-2 traffic, such as ping, if your network configuration has:

- packets going through the FortiGate unit in transparent mode more than once
- more than one forwarding domain (such as incoming on one forwarding domain and outgoing on another)
- IPS and AV enabled.

Now IPS and AV is applied the first time packets go through the FortiGate unit, but not on subsequent passes. Only applying IPS and AV to this first pass fixes the network layer-2 related connection issues.

## NetBIOS

Computers running Microsoft Windows operating systems that are connected through a network rely on a WINS server to resolve host names to IP addresses. The hosts communicate with the WINS server by using the NetBIOS protocol.

To support this type of network, you need to enable the forwarding of NetBIOS requests to a WINS server. The following example will forward NetBIOS requests on the internal interface for the WINS server located at an IP address of 192.168.111.222.

```

config system interface
    edit internal
        set netbios_forward enable
        set wins-ip 192.168.111.222
    end

```

These commands apply only in NAT mode. If VDOMs are enabled, these commands are per VDOM. You must set them for each VDOM that has the problem.

## STP forwarding

The FortiGate unit does not participate in the Spanning Tree Protocol (STP). STP is an IEEE 802.1 protocol that ensures there are no layer-2 loops on the network. Loops are created when there is more than one route for traffic to take and that traffic is broadcast back to the original switch. This loop floods the network with traffic, reducing available bandwidth to nothing.

If you use your FortiGate unit in a network topology that relies on STP for network loop protection, you need to make changes to your FortiGate configuration. Otherwise, STP recognizes your FortiGate unit as a blocked link and forwards the data to another path. By default, your FortiGate unit blocks STP as well as other non-IP protocol traffic.

Using the CLI, you can enable forwarding of STP and other layer-2 protocols through the interface. In this example, layer-2 forwarding is enabled on the external interface:

```
config system interface
  edit external
    set l2forward enable
    set stpforward enable
  end
```

By substituting different commands for `stpforward enable`, you can also allow layer-2 protocols such as IPX, PPTP or L2TP to be used on the network. For more information, see [“Layer-2 and Arp traffic” on page 1551](#).

## Too many VLAN interfaces

Any virtual domain can have a maximum of 255 interfaces in transparent mode. This includes VLANs, other virtual interfaces, and physical interfaces. NAT mode supports from 255 to 8192 depending on the FortiGate model. This total number of interfaces includes VLANs, other virtual interfaces, and physical interfaces.

Your FortiGate unit may allow you to configure more interfaces than this. However, if you configure more than 255 interfaces, your system will become unstable and, over time, will not work properly. As all interfaces are used, they will overflow the routing table that stores the interface information, and connections will fail. When you try to add more interfaces, an error message will state that the maximum limit has already been reached.

If you see this error message, chances are you already have too many VLANs on your system and your routing has become unstable. To verify, delete a VLAN and try to add it back. If you have too many, you will not be able to add it back on to the system. In this case, you will need to remove enough interfaces (including VLANs) so that the total number of interfaces drops to 255 or less. After doing this, you should also reboot your FortiGate unit to clean up its memory and buffers, or you will continue to experience unstable behavior.

To configure more than 255 interfaces on your FortiGate unit in transparent mode, you have to configure multiple VDOMs, each with many VLANs. However, if you want to create more than the default 10 VDOMs (or a maximum of 2550 interfaces), you must buy a license for additional VDOMs.

With these extra licenses, you can configure up to 500 VDOMs, with each VDOM containing up to 255 VLANs in transparent mode. This is a theoretical maximum of over 127 500 interfaces. However, system resources will quickly get used up before reaching that theoretical maximum. To achieve the maximum number of VDOMs, you need to have top-end hardware with the most resources possible.

In NAT mode, if you have a top-end model, the maximum interfaces per VDOM can be as high as 8192, enough for all the VLANs in your configuration.

Your FortiGate unit has limited resources, such as CPU load and memory, that are divided between all configured VDOMs. When running 250 or more VDOMs, you may need to monitor the system resources to ensure there is enough to support the configured traffic processing.

---

# PPTP and L2TP

A virtual private network (VPN) is a way to use a public network, such as the Internet, as a vehicle to provide remote offices or individual users with secure access to private networks. FortiOS supports the Point-to-Point Tunneling Protocol (PPTP), which enables interoperability between FortiGate units and Windows or Linux PPTP clients. Because FortiGate units support industry standard PPTP VPN technologies, you can configure a PPTP VPN between a FortiGate unit and most third-party PPTP VPN peers.

This section describes how to configure PPTP and L2TP VPNs as well as PPTP passthrough.

This section includes the topics:

- [How PPTP VPNs work](#)
- [FortiGate unit as a PPTP server](#)
- [Configuring the FortiGate unit for PPTP VPN](#)
- [Configuring the FortiGate unit for PPTP pass through](#)
- [Testing PPTP VPN connections](#)
- [Logging VPN events](#)
- [Configuring L2TP VPNs](#)
- [L2TP configuration overview](#)

## How PPTP VPNs work

The Point-to-Point Tunneling Protocol enables you to create a VPN between a remote client and your internal network. Because it is a Microsoft Windows standard, PPTP does not require third-party software on the client computer. As long as the ISP supports PPTP on its servers, you can create a secure connection by making relatively simple configuration changes to the client computer and the FortiGate unit.

PPTP uses Point-to-Point protocol (PPP) authentication protocols so that standard PPP software can operate on tunneled PPP links. PPTP packages data in PPP packets and then encapsulates the PPP packets within IP packets for transmission through a VPN tunnel.

When the FortiGate unit acts as a PPTP server, a PPTP session and tunnel is created as soon as the PPTP client connects to the FortiGate unit. More than one PPTP session can be supported on the same tunnel. FortiGate units support PAP, CHAP, and plain text authentication. PPTP clients are authenticated as members of a user group.

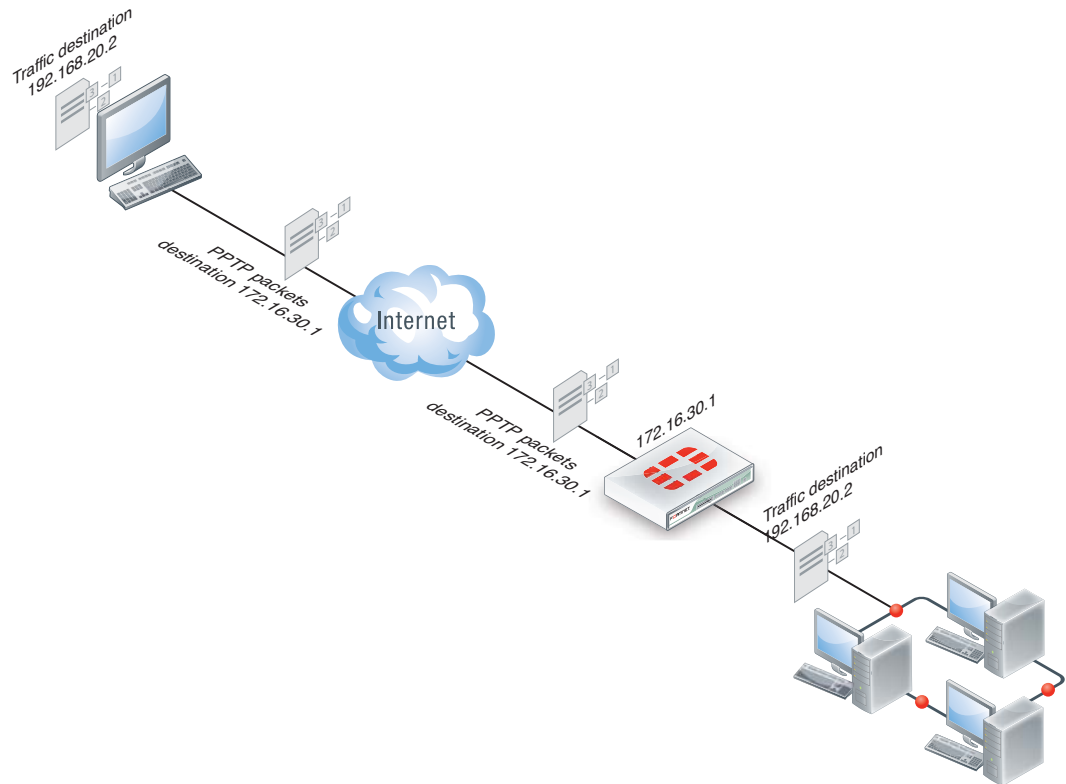

Traffic from one PPTP peer is encrypted using PPP before it is encapsulated using Generic Routing Encapsulation (GRE) and routed to the other PPTP peer through an ISP network. PPP packets from the remote client are addressed to a computer on the private network behind the FortiGate unit. PPTP packets from the remote client are addressed to the public interface of the FortiGate unit. See [Figure 242 on page 1556](#)

PPTP control channel messages are not authenticated, and their integrity is not protected. Furthermore, encapsulated PPP packets are not cryptographically protected and may be read or modified unless appropriate encryption software such as Secure Shell (SSH) or Secure File Transfer Protocol (SFTP) is used to transfer data after the tunnel has been established.

As an alternative, you can use encryption software such as Microsoft Point-to-Point Encryption (MPPE) to secure the channel. MPPE is built into Microsoft Windows clients and can be installed on Linux clients. FortiGate units support MPPE.

**Figure 242:**Packet encapsulation

In [Figure 242](#), traffic from the remote client is addressed to a computer on the network behind the FortiGate unit. When the PPTP tunnel is established, packets from the remote client are encapsulated and addressed to the FortiGate unit. The FortiGate unit forwards disassembled packets to the computer on the internal network.

When the remote PPTP client connects, the FortiGate unit assigns an IP address from a reserved range of IP addresses to the client PPTP interface. The PPTP client uses the assigned IP address as its source address for the duration of the connection.

When the FortiGate unit receives a PPTP packet, the unit disassembles the PPTP packet and forwards the packet to the correct computer on the internal network. The security policy and protection profiles on the FortiGate unit ensure that inbound traffic is screened and processed securely.

PPTP clients must be authenticated before a tunnel is established. The authentication process relies on FortiGate user group definitions, which can optionally use established authentication mechanisms such as RADIUS or LDAP to authenticate PPTP clients. All PPTP clients are challenged when a connection attempt is made.

## FortiGate unit as a PPTP server

In the most common Internet scenario, the PPTP client connects to an ISP that offers PPP connections with dynamically-assigned IP addresses. The ISP forwards PPTP packets to the Internet, where they are routed to the FortiGate unit.

**Figure 243:**FortiGate unit as a PPTP server

If the FortiGate unit will act as a PPTP server, there are a number of steps to complete:

- Configure user authentication for PPTP clients.
- Enable PPTP.
- Specify the range of addresses that are assigned to PPTP clients when connecting
- Configure the security policy.

### Configuring user authentication for PPTP clients

To enable authentication for PPTP clients, you must create user accounts and a user group to identify the PPTP clients that need access to the network behind the FortiGate unit. Within the user group, you must add a user for each PPTP client.

You can choose to use a plain text password for authentication or forward authentication requests to an external RADIUS, LDAP, or TACACS+ server. If password protection will be provided through a RADIUS, LDAP, or TACACS+ server, you must configure the FortiGate unit to forward authentication requests to the authentication server.

This example creates a basic user/password combination.

#### Configuring a user account

##### To add a local user - web-based manager

1. Go to *User & Device > User > User Definition* and select *Create New*.
2. Enter a *User Name*.
3. Enter a *Password* for the user. The password should be at least six characters.
4. Select *OK*.

### To add a local user - CLI

```
config user local
  edit <username>
    set type password
    set passwd <password>
  end
```

## Configuring a user group

To ease configuration, create user groups that contain users in similar categories or departments.

### To create a user group - web-based manager

1. Go to *User & Device > User > User Group* and select *Create New*.
2. Enter a *Name* for the group.
3. Select the *Type of Firewall*.
4. From the *Available Users* list, select the required users and select the right-facing arrow to add them to the *Members* list.
5. Select *OK*.

### To create a user group - CLI

```
config user group
  edit <group_name>
    set group-type firewall
    set members <user_names>
  end
```

## Enabling PPTP and specifying the PPTP IP address range

The PPTP address range specifies the range of addresses reserved for remote PPTP clients. When a PPTP client connects to the FortiGate unit, the client is assigned an IP address from this range. Afterward, the FortiGate unit uses the assigned address to communicate with the PPTP client.

The address range that you reserve can be associated with private or routable IP addresses. If you specify a private address range that matches a network behind the FortiGate unit, the assigned address will make the PPTP client appear to be part of the internal network.

PPTP requires two IP addresses, one for each end of the tunnel. The PPTP address range is the range of addresses reserved for remote PPTP clients. When the remote PPTP client establishes a connection, the FortiGate unit assigns an IP address from the reserved range of IP addresses to the client PPTP interface or retrieves the assigned IP address from the PPTP user group. If you use the PPTP user group, you must also define the FortiGate end of the tunnel by entering the IP address of the unit in *Local IP* (web-based manager) or `local-ip` (CLI). The PPTP client uses the assigned IP address as its source address for the duration of the connection.

PPTP configuration is only available through the CLI. In the example below, PPTP is enabled with the use of an IP range of 192.168.1.1 to 192.168.1.10 for addressing.

The start and end IPs in the PPTP address range must be in the same 24-bit subnet, for example, 192.168.1.1 - 192.168.1.254.

```

config vpn pptp
    set status enable
    set ip-mode range
    set eip 192.168.1.10
    set sip 192.168.1.1
end

```

In this example, PPTP is enabled with the use of a user group for addressing, where the IP address of the PPTP server is 192.168.1.2 and the user group is hr\_admin.

```

config vpn pptp
    set status enable
    set ip-mode range
    set local-ip 192.168.2.1
    set usrgrp hr_admin
end

```

## Adding the security policy

The security policy specifies the source and destination addresses that can generate traffic inside the PPTP tunnel and defines the scope of services permitted through the tunnel. If a selection of services are required, define a service group.

### To configure the firewall for the PPTP tunnel - web-based manager

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
3. Complete the following and select *OK*:

<b>Incoming Interface</b>	The FortiGate interface connected to the Internet.
<b>Source Address</b>	Select the name that corresponds to the range of addresses that you reserved for PPTP clients.
<b>Outgoing Interface</b>	The FortiGate interface connected to the internal network.
<b>Destination Address</b>	Select the name that corresponds to the IP addresses behind the FortiGate unit.
<b>Schedule</b>	always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT

Do not select identity-based policy, as this will cause the PPTP access to fail. Authentication is configured in the PPTP configuration setup

### To configure the firewall for the PPTP tunnel - CLI

```
config firewall policy
  edit 1
    set srcintf <interface to internet>
    set dstintf <interface to internal network>
    set srcaddr <reserved_range>
    set dstaddr <internal_addresses>
    set action accept
    set schedule always
    set service ALL
  end
```

## Configuring the FortiGate unit for PPTP VPN

To arrange for PPTP packets to pass through the FortiGate unit to an external PPTP server, perform the following tasks in the order given:

- Configure user authentication for PPTP clients.
- Enable PPTP on the FortiGate unit and specify the range of addresses that can be assigned to PPTP clients when they connect.
- Configure PPTP pass through on the FortiGate unit.

## Configuring the FortiGate unit for PPTP pass through

To forward PPTP packets to a PPTP server on the network behind the FortiGate unit, you need to perform the following configuration tasks on the FortiGate unit:

- Define a virtual IP address that points to the PPTP server.
- Create a security policy that allows incoming PPTP packets to pass through to the PPTP server.

The address range is the external (public) ip address range which requires access to the internal PPTP server through the FortiGate virtual port-forwarding firewall.

IP addresses used in this document are fictional and follow the technical documentation guidelines specific to Fortinet. Real external IP addresses are not used.

### Configuring a virtual IP address

The virtual IP address will be the address of the PPTP server host.

#### To define a virtual IP for PPTP pass through - web-based manager

1. Go to *Firewall Objects > Virtual IP > Virtual IP*.
2. Select *Create New*.
3. Enter the name of the VIP, for example, *PPTP\_Server*.
4. Select the *External Interface* where the packets will be received for the PPTP server.
5. Enter the *External IP Address* for the VIP.
6. Select *Port Forwarding*.
7. Set the *Protocol to TCP*.

8. Enter the *External Service Port* of 1723, the default for PPTP.
9. Enter the *Map to Port* to 1723.
10. Select OK.

#### To define a virtual IP for PPTP pass through - web-based manager

```
config firewall vip
    edit PPTP_Server
        set extintf <interface>
        set extip <ip_address>
        set portforward enable
        set protocol tcp
        set extport 1723
        set mappedport 1723
    end
```

## Configuring a port-forwarding security policy

To create a port-forwarding security policy for PPTP pass through you must first create an address range reserved for the PPTP clients.

#### To create an address range - web-based manager

1. Go to *Firewall Objects > Address > Addresses* and select *Create New*.
2. Enter a *Name* for the range, for example, *External\_PPTP*.
3. Select a *Type* of *Subnet/IP Range*.
4. Enter the IP address range.
5. Select the *Interface* to the Internet.
6. Select OK.

#### To create an address range - CLI

```
config firewall address
    edit External_PPTP
        set iprange <ip_range>
        set start-ip <ip_address>
        set end-ip <ip_address>
        set associated-interface <internet_interface>
    end
```

With the address set, you can add the security policy.

#### To add the security policy - web-based manager

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
3. Complete the following and select OK:

<b>Incoming Interface</b>	The FortiGate interface connected to the Internet.
<b>Source Address</b>	Select the address range created in the previous step.
<b>Outgoing Interface</b>	The FortiGate interface connected to the PPTP server.
<b>Destination Address</b>	Select the VIP address created in the previous steps.

<b>Schedule</b>	always
<b>Service</b>	PPTP
<b>Action</b>	ACCEPT

#### To add the security policy - CLI

```
config firewall policy
    edit <policy_number>
        set srcintf <interface to internet>
        set dstintf <interface to PPTP server>
        set srcaddr <address_range>
        set dstaddr <PPTP_server_address>
        set action accept
        set schedule always
        set service PPTP
    end
```

## Testing PPTP VPN connections

To confirm that a PPTP VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The PPTP VPN tunnel initializes when the dialup client attempts to connect.

## Logging VPN events

PPTP VPN, activity is logged when enabling VPN logging. The FortiGate unit connection events and tunnel status (up/down) are logged.

#### To log VPN events

1. Go to *Log & Report > Log Config > Log Settings*.
2. Enable the storage of log messages to one or more locations.
3. Select *VPN activity event*.
4. Select *Apply*.

#### To view event logs

1. Go to *Log & Report > Event Log > VPN*.
2. If the option is available from the Log Type list, select the log file from disk or memory.

## Configuring L2TP VPNs

This section describes how to configure a FortiGate unit to establish a Layer Two Tunneling Protocol (L2TP) tunnel with a remote dialup client. The FortiGate implementation of L2TP enables a remote dialup client to establish an L2TP tunnel with the FortiGate unit directly.

According to RFC 2661, an Access Concentrator (LAC) can establish an L2TP tunnel with an L2TP Network Server (LNS). In a typical scenario, the LAC is managed by an ISP and located on the ISP premises; the LNS is the gateway to a private network. When a remote dialup client connects to the Internet through the ISP, the ISP uses a local database to establish the identity

of the caller and determine whether the caller needs access to an LNS through an L2TP tunnel. If the services registered to the caller indicate that an L2TP connection to the LNS is required, the ISP LAC attempts to establish an L2TP tunnel with the LNS.

A FortiGate unit can be configured to act as an LNS. The FortiGate implementation of L2TP enables a remote dialup client to establish an L2TP tunnel with the FortiGate unit directly, bypassing any LAC managed by an ISP. The ISP must configure its network access server to forward L2TP traffic from the remote client to the FortiGate unit directly whenever the remote client requires an L2TP connection to the FortiGate unit.

When the FortiGate unit acts as an LNS, an L2TP session and tunnel is created as soon as the remote client connects to the FortiGate unit. The FortiGate unit assigns an IP address to the client from a reserved range of IP addresses. The remote client uses the assigned IP address as its source address for the duration of the connection.

More than one L2TP session can be supported on the same tunnel. FortiGate units can be configured to authenticate remote clients using a plain text user name and password, or authentication can be forwarded to an external RADIUS or LDAP server. L2TP clients are authenticated as members of a user group.

FortiGate units support L2TP with Microsoft Point-to-Point Encryption (MPPE) encryption only. Later implementations of Microsoft L2TP for Windows use IPsec and require certificates for authentication and encryption. If you want to use Microsoft L2TP with IPsec to connect to a FortiGate unit, the IPsec and certificate elements must be disabled on the remote client

Traffic from the remote client must be encrypted using MPPE before it is encapsulated and routed to the FortiGate unit. Packets originating at the remote client are addressed to a computer on the private network behind the FortiGate unit. Encapsulated packets are addressed to the public interface of the FortiGate unit. See [Figure 244](#).

When the FortiGate unit receives an L2TP packet, the unit disassembles the packet and forwards the packet to the correct computer on the internal network. The security policy and protection profiles on the FortiGate unit ensure that inbound traffic is screened and processed securely.

**Figure 244:**L2TP encapsulation

FortiGate units cannot deliver non-IP traffic such as Frame Relay or ATM frames encapsulated in L2TP packets — FortiGate units support the IPv4 and IPv6 addressing schemes only

## Network topology

The remote client connects to an ISP that determines whether the client requires an L2TP connection to the FortiGate unit. If an L2TP connection is required, the connection request is forwarded to the FortiGate unit directly.

**Figure 245:**Example L2TP configuration

## L2TP infrastructure requirements

- The FortiGate unit must be operating in NAT mode and have a static public IP address.
- The ISP must configure its network access server to forward L2TP traffic from remote clients to the FortiGate unit directly.
- The remote client must not generate non-IP traffic (Frame Relay or ATM frames).
- The remote client includes L2TP support with MPPE encryption. If the remote client includes Microsoft L2TP with IPSec, the IPSec and certificate components must be disabled.

## L2TP configuration overview

To configure a FortiGate unit to act as an LNS, you perform the following tasks:

- Create an L2TP user group containing one user for each remote client.
- Enable L2TP on the FortiGate unit and specify the range of addresses that can be assigned to remote clients when they connect.
- Define firewall source and destination addresses to indicate where packets transported through the L2TP tunnel will originate and be delivered.
- Create the security policy and define the scope of permitted services between the source and destination addresses.
- Configure the remote clients.

## Authenticating L2TP clients

L2TP clients must be authenticated before a tunnel is established. The authentication process relies on FortiGate user group definitions, which can optionally use established authentication mechanisms such as RADIUS or LDAP to authenticate L2TP clients. All L2TP clients are challenged when a connection attempt is made.

To enable authentication, you must create user accounts and a user group to identify the L2TP clients that need access to the network behind the FortiGate unit.

You can choose to use a plain text password for authentication or forward authentication requests to an external RADIUS or LDAP server. If password protection will be provided through a RADIUS or LDAP server, you must configure the FortiGate unit to forward authentication requests to the authentication server.

## Enabling L2TP and specifying an address range

The L2TP address range specifies the range of addresses reserved for remote clients. When a remote client connects to the FortiGate unit, the client is assigned an IP address from this range. Afterward, the FortiGate unit uses the assigned address to communicate with the remote client.

The address range that you reserve can be associated with private or routable IP addresses. If you specify a private address range that matches a network behind the FortiGate unit, the assigned address will make the remote client appear to be part of the internal network.

To enable L2TP and specify the L2TP address range, use the `config vpn l2tp` CLI command.

The following example shows how to enable L2TP and set the L2TP address range using a starting address of 192.168.10.80 and an ending address of 192.168.10.100 for an existing group of L2TP users named L2TP\_users:

```
config vpn l2tp
  set sip 192.168.10.80
  set eip 192.168.10.100
  set status enable
  set usrgrp L2TP_users
end
```

## Defining firewall source and destination addresses

Before you define the security policy, you must define the source and destination addresses of packets that are to be transported through the L2TP tunnel:

- For the source address, enter the range of addresses that you reserved for remote L2TP clients (for example 192.168.10.[80-100]).
- For the destination address, enter the IP addresses of the computers that the L2TP clients need to access on the private network behind the FortiGate unit (for example, 172.16.5.0/24 for a subnet, or 172.16.5.1 for a server or host, or 192.168.10.[10-15] for an IP address range).

### To define the firewall source address

1. Go to *Firewall Objects > Address > Addresses* and select *Create New*.
2. In the *Address Name* field, type a name that represents the range of addresses that you reserved for remote clients (for example, Ext\_L2TPrange).
3. In *Type*, select *Subnet / IP Range*.

4. In the *Subnet / IP Range* field, type the corresponding IP address range.
5. In *Interface*, select the FortiGate interface that connects to the clients.
6. This is usually the interface that connects to the Internet.
7. Select *OK*.

#### To define the firewall destination address

1. Go to *Firewall Objects > Address > Addresses* and select *Create New*.
2. In the *Address Name* field, type a name that represents a range of IP addresses on the network behind the FortiGate unit (for example, *Int\_L2TPaccess*).
3. In *Type*, select *Subnet / IP Range*.
4. In the *Subnet / IP Range* field, type the corresponding IP address range.
5. In *Interface*, select the FortiGate interface that connects to the network behind the FortiGate unit.
6. Select *OK*.

## Adding the security policy

The security policy specifies the source and destination addresses that can generate traffic inside the L2TP tunnel and defines the scope of services permitted through the tunnel. If a selection of services are required, define a service group.

#### To define the traffic and services permitted inside the L2TP tunnel

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and the *Policy Subtype* as *Address*.
3. Enter these settings:

<b>Incoming Interface</b>	Select the FortiGate interface to the Internet.
<b>Source Address</b>	Select the name that corresponds to the address range that reserved for L2TP clients (for example, <i>Ext_L2TPrange</i> ).
<b>Outgoing Interface</b>	Select the FortiGate interface to the internal (private) network.
<b>Destination Address</b>	Select the name that corresponds to the IP addresses behind the FortiGate unit (for example, <i>Int_L2TPaccess</i> ).
<b>Service</b>	Select ALL, or if selected services are required instead, select the service group that you defined previously.
<b>Action</b>	ACCEPT

4. Select *OK*.

## Configuring a Linux client

This procedure outlines how to install L2TP client software and run an L2TP tunnel on a Linux computer. Obtain an L2TP client package that meets your requirements (for example, *rp-l2tp*). If needed to encrypt traffic, obtain L2TP client software that supports encryption using MPPE.

To establish an L2TP tunnel with a FortiGate unit that has been set up to accept L2TP connections, you can obtain and install the client software following these guidelines:

1. If encryption is required but MPPE support is not already present in the kernel, download and install an MPPE kernel module and reboot your computer.
2. Download and install the L2TP client package.
3. Configure an L2TP connection to run the L2TP program.
4. Configure routes to determine whether all or some of your network traffic will be sent through the tunnel. You must define a route to the remote network over the L2TP link and a host route to the FortiGate unit.
5. Run `l2tpd` to start the tunnel.

Follow the software supplier's documentation to complete the steps.

To configure the system, you need to know the public IP address of the FortiGate unit, and the user name and password that has been set up on the FortiGate unit to authenticate L2TP clients. Contact the FortiGate administrator if required to obtain this information.

## Monitoring L2TP sessions

You can display a list of all active sessions and view activity by port number. By default, port 1701 is used for L2TP VPN-related communications. If required, active sessions can be stopped from this view. Use the Top Sessions Dashboard Widget.

## Testing L2TP VPN connections

To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

## Logging L2TP VPN events

You can configure the FortiGate unit to log VPN events. For L2TP VPNs, connection events and tunnel status (up/down) are logged.

### To log VPN events - web-based manager

1. Go to *Log & Report > Log Config > Log Settings*.
2. Enable the storage of log messages to one or more locations.
3. Select *Enable*, and then select *VPN activity event*.
4. Select *Apply*.

### To log VPN events - CLI

```
config log memory setting
    set diskfull overright
    set status enable
end
config log eventfilter
    set ppp
end
```

# Advanced concepts

This chapter provides configuration concepts and techniques to enhance your network security.

This section includes the topics:

- [Dual internet connections \(redundant Internet connections\)](#)
- [Single firewall vs. multiple virtual domains](#)
- [Modem](#)
- [DHCP servers and relays](#)
- [Assigning IP address by MAC address](#)
- [DNS services](#)
- [Dynamic DNS](#)
- [FortiClient discovery and registration](#)
- [IP addresses for self-originated traffic](#)
- [Administration for schools](#)
- [Tag management](#)
- [Replacement messages list](#)
- [Disk](#)
- [CLI Scripts](#)
- [Rejecting PING requests](#)
- [Opening TCP 113](#)
- [Obfuscate HTTP responses](#)

## Dual internet connections (redundant Internet connections)

Dual internet connection, dual WAN, or redundant internet connection refers to using two FortiGate interfaces to connect to the Internet. Dual internet connections can be used in three ways:

- redundant interfaces, should one interface go down, the second automatically becomes the main internet connection
- for load sharing to ensure better throughput.
- a combination of redundancy and load sharing.

### Redundant interfaces

Redundant interfaces, ensures that should your internet access be no longer available through a certain port, the FortiGate unit will use an alternate port to connect to the Internet.

**Figure 246:**Configuring redundant interfaces

In this scenario, two interfaces, WAN1 and WAN2 are connected to the Internet using two different ISPs. WAN1 is the primary connection. In an event of a failure of WAN1, WAN2 automatically becomes the connection to the Internet. For this configuration to function correctly, you need to configure three specific settings:

- configure a ping server to determine when the primary interface (WAN1) is down and when the connection returns
- configure a default route for each interface.
- configure security policies to allow traffic through each interface to the internal network.

### Ping server

Adding a ping server is required for routing fail over traffic. A ping server will confirm the connectivity of the device's interface

#### To add a ping server - web-based manager

1. Go to *Router > Static > Settings* and select *Create New*.  
For low-end FortiGate units, go to *System > Network > Routing* and select *Create New*.
2. Select the *Interface* that will send ping requests.
3. For the *Ping Server* field, enter the IP address of a server that the FortiGate unit will send ping requests to. This is typically a next hop router or gateway device.
4. Select the *Detect Protocol* type.
5. For the *Ping Interval*, enter the number of seconds to send ping requests.
6. For the *Failover Threshold*, enter the number of lost pings is acceptable before the port is determined to be down.
7. Select *OK*.

### To add a ping server - CLI

```
config router gwdetect
  edit wan1
    set server <ISP_IP_address>
    set failtime <failure_count>
    set interval <seconds>
  end
```

## Routing

You need to configure a default route for each interface and indicate which route is preferred by specifying the distance. The lower distance is declared active and placed higher in the routing table.

When you have dual WAN interfaces that are configured to provide fail over, you might not be able to connect to the backup WAN interface because the FortiGate unit may not route traffic (even responses) out of the backup interface. The FortiGate unit performs a reverse path lookup to prevent spoofed traffic. If no entry can be found in the routing table which sends the return traffic out the same interface, then the incoming traffic is dropped.

### To configure the routing of the two interfaces - web-based manager

1. Go to *Router > Static > Static Routes* and select *Create New*.  
For low-end FortiGate units, go to *System > Network > Routing* and select *Create New*.
2. Set the *Destination IP/Mask* to the address and netmask to 0.0.0.0/0.0.0.0.
3. Select the *Device* to the primary connection, *WAN1*.
4. Enter the *Gateway* address.
5. Select *Advanced*.
6. Set the *Distance* to 10.
7. Select *OK*.
8. Repeat steps 1 through 7 setting the *Device* to *WAN2* and a *Distance* of 20.

### To configure the routing of the two interfaces - CLI

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set device WAN1
    set gateway 0.0.0.0 0.0.0.0
    set distance 10
  next
  edit 1
    set dst <ISP_Address>
    set device WAN2
    set gateway <gateway_address>
    set distance 20
  next
end
```

## Security policies

When creating security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic will be allowed to pass through WAN2 as it did with WAN1. This ensures that fail-over will occur with minimal affect to users. For more information on creating security policies see the [Firewall](#) Guide.

## Load sharing

Load sharing enables you to use both connections to the internet at the same time, but do not provide fail over support. When configuring for load sharing, you need to ensure routing is configured for both external ports, for example, WAN1 and WAN2, have static routes with the same distance and priority.

Further configuration can be done using Equal Cost Multiple Path (ECMP). For more information on ECMP and load sharing, see the [Advanced Routing](#) Guide.

## Link redundancy and load sharing

In this scenario, both links are available to distribute Internet traffic over both links. Should one of the interfaces fail, the FortiGate unit will continue to send traffic over the other active interface. Configuration is similar to the [Redundant interfaces](#) configuration, with the main difference being that the configured routes should have equal distance settings.

This means both routes will remain active in the routing table. To make one interface the preferred interface, use a default policy route to indicate the interface that is preferred for accessing the Internet. If traffic matches the security policy, the policy overrides all entries in the routing table, including connected routes. You may need to add a specific policy routes that override these default policy routes.

To redirect traffic over the secondary interface, create policy routes to direct some traffic onto it rather than the primary interface. When adding the policy route, only define the outgoing interface and leave the gateway blank. This ensures that the policy route will not be active when the link is down.

## Single firewall vs. multiple virtual domains

A typical FortiGate setup, with a small to mid-range appliance, enables you to include a number of subnets on your network using the available ports and switch interfaces. This can potentially provide a means of having three or more mini networks for the various groups in a company. Within this infrastructure, multiple network administrators have access to the FortiGate to maintain security policies.

However, the FortiGate unit may not have enough interfaces to match the number of departments in the organization. If the FortiGate unit is running in transparent mode however, there is only one interface, and multiple network branches through the FortiGate are not possible.

A FortiGate unit with Virtual Domains (VDOMs) enabled, provides a means to provide the same functionality in transparent mode as a FortiGate in NAT mode. VDOMs are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. VDOMs can provide separate security policies and, in NAT mode, completely separate configurations for routing and VPN services for each connected network. For administration, an administrator can be assigned to each VDOM, minimizing the possibility of error or fouling network communications.

By default, your FortiGate unit supports a maximum of 10 VDOMs. For select FortiGate models you can purchase a license key to increase the number of VDOMs.

The FortiGate-20C and 30B and FortiWifi-20C and 30B do not support VDOMs.

## Single firewall vs. vdoms

When VDOMs are not enabled, and the FortiGate unit is in transparent mode, all the interfaces on your unit become broadcast interfaces. The problem is there are no interfaces free for additional network segments.

A FortiGate with three interfaces means only limited network segments are possible without purchasing more FortiGate devices.

With multiple VDOMs you can have one of them configured in transparent mode, and the rest in NAT mode. In this configuration, you have an available transparent mode FortiGate unit you can drop into your network for troubleshooting, and you also have the standard.

This example shows how to enable VDOMs on the FortiGate unit and the basic and create a VDOM accounting on the DMZ2 port and assign an administrator to maintain the VDOM. First enable Virtual Domains on the FortiGate unit.

### To enable VDOMs - web-based manager

1. Go to *System > Dashboard > Status*.
2. In the *System Information* widget, select *Enable for Virtual Domain*.

Note that on FortiGate-60 series and lower models, you need to enable VDOMs in the CLI only.

The FortiGate unit logs you out. Once you log back in, you will notice that the menu structure has changed. This reflects the global settings for all Virtual Domains.

### To enable VDOMs - CLI

```
config system global
    set vdom-admin enable
end
```

Next, add the VDOM called accounting.

### To add a VDOM - web-based manager

1. Go to *Global > VDOM > VDOM*, and select *Create New*.
2. Enter the VDOM name *accounting*.
3. Select *OK*.

### To add a VDOM - CLI

```
config vdom
    edit <new_vdom_name>
end
```

With the Virtual Domain created, you can assign a physical interface to it, and assign it an IP address.

### To assign physical interface to the accounting Virtual Domain - web-based manager

1. Go to *Global > Network > Interface*.
2. Select the DMZ2 port row and select *Edit*.
3. For the *Virtual Domain* drop-down list, select *accounting*.
4. Select the *Addressing Mode* of *Manual*.
5. Enter the IP address for the port of 10.13.101.100/24.
6. Set the *Administrative Access* to *HTTPS* and *SSH*.
7. Select *OK*.

### To assign physical interface to the accounting Virtual Domain - CLI

```
config global
    config system interface
        edit dmz2
            set vdom accounting
            set ip 10.13.101.100/24
            set allowaccess https ssh
        next
    end
```

## Modem

FortiGate units support the use of wireless, 3G and 4G modems connected using the USB port or, if available, the express card slot. Modem access provides either primary or secondary (redundant) access to the Internet. For FortiGate units that do not include an internal modem (those units with an “M” designation), the modem interface will not appear in the web-based manager until enabled in the CLI. To enable the modem interface enter the CLI commands:

```
config system modem
    set status enable
end
```

You will need to log out of the FortiGate and log back in to see the modem configuration page at *System > Network > Modem*. Once enabled, modem options become available by going to *System > Network > Interface*.

Note that the modem interface is only available when the FortiGate unit is in NAT mode.

To configure modem settings, go to *System > Network > Modem*.

Configuring the modem settings is a matter of entering the ISP phone number, user name and password. Depending on the modem, additional information may need to be supplied such as product identifiers, and initialization strings.

The FortiGate unit includes a number of common modems within its internal database. You can view these by selecting the *Configure Modem* link on the *Modem Settings* page. If your modem is not on the list, select *Create New* to add the information. This information is stored on the device, and will remain after a reboot.

Fortinet has an online database of modem models and configuration settings through FortiGuard. A subscription to the FortiGuard services is not required to access the information. As models are added, you can select the *Configure Modem* link and select *Update Now* to download new configurations.

## USB modem port

Each USB modem has a specific dial-out ttyusb port. This will be indicated with the documentation for your modem. To enable the correct USB port, use the CLI commands:

```
config system modem
    set wireless-port {ttyusb0 | ttyusb1 | ttyusb2}
end
```

To test the port, use the diagnose command:

```
diagnose sys modem com /ttyusb1
```

The ttyusb1 will be the value of your USB port selected. The response will be:

```
Serial port: /dev/ttyusb1
Press Ctrl+W to exit.
```

If the port does not respond the output will be:

```
Can not open modem device '/dev/ttyusb1' : Broken pipe
```

## Modes

The FortiGate unit allows for two modes of operation for the modem; stand alone and redundant. In stand alone mode, the modem connects to a dialup ISP account to provide the connection to the Internet. In redundant mode, the modem acts as a backup method of connecting to the Internet, should the primary port for this function fails.

Configuring either stand alone or redundant modes are very similar. The primary difference is the selection of the interface that the modem will replace in the event of it failing, and the configuration of a PING server to monitor the chosen interface.

### Configuring stand alone mode

Configuring stand alone mode is a matter of configuring the modem information and the dialing mode. The dial mode is either *Always Connect* or *Dial on demand*. Selecting *Always Connect* ensures that once the modem has connected, it remains connected to the ISP. Selecting *Dial on Demand*, the modem only calls the ISP if packets are routed to the modem interface. Once sent, the modem will disconnect after a specified amount of time.

#### To configure standalone mode as needed - web-based manager

1. Go to *System > Network > Modem*.
2. Select the *Mode of Standalone*.
3. Select the *Dial Mode of Dial on Demand*.
4. Enter the *Idle Timeout* of 2 minutes.
5. Select the number of redials the modem attempts if connection fails to 5.
6. Select *Apply*.

#### To configure standalone mode as needed- CLI

```
config system modem
    set mode standalone
    set auto-dial enable
    set idle-timer 2
    set redial 5
end
```

### Configuring redundant mode

Redundant mode provides a backup to an interface, typically to the Internet. If that interface fails or disconnects, the modem automatically dials the configured phone number(s). Once connected, the FortiGate unit routes all traffic to the modem interface until the monitored interface is up again. The FortiGate unit pings the connection to determine when it is back online.

For the FortiGate to verify when the interface is back up, you need to configure a Ping server for that interface. You will also need to configure security policies between the modem interface and the other interfaces of the FortiGate unit to ensure traffic flow.

#### To configure redundant mode as needed - web-based manager

1. Go to *System > Network > Modem*.
2. Select the *Mode of Redundant*.
3. Select the interface the modem takes over from if it fails.
4. Select the *Dial Mode of Dial on Demand*.
5. Enter the *Idle Timeout* of 2 minutes.
6. Select the number of redials the modem attempts if connection fails to 5.
7. Select *Apply*.

### To configure standalone mode as needed- CLI

```
config system modem
    set mode redundant
    set interface wan1
    set auto-dial enable
    set idle-timer 2
    set redial 5
end
```

### Ping server

Adding a ping server is required for routing fail over traffic. A ping server will confirm the connectivity of the device's interface.

For low-end FortiGate units, go to *System > Admin > Settings* and enable *Dynamic Routing* before continuing.

#### To add a ping server - web-based manager

1. Go to *Router > Static > Settings* and select *Create New*.
2. Select the *Interface* that will send ping requests.
3. For the *Ping Server* field, enter the IP address of a server that the FortiGate unit will send ping requests to. This is typically a next hop router or gateway device.
4. Select the *Detect Protocol* type *ICMP Ping*.
5. For the *Ping Interval*, enter the number of seconds to send ping requests.
6. For the *Failover Threshold*, enter the number of lost pings is acceptable before the port is determined to be down.
7. Select *OK*.

#### To add a ping server - CLI

```
config router gwdetect
    edit wan1
        set server <ISP_IP_address>
        set failtime <failure_count>
        set interval <seconds>
    end
```

### Additional modem configuration

The CLI provides additional configuration options when setting up the modem options including adding multiple ISP dialing and initialization options and routing. For more information, see the [CLI Reference](#).

### Modem interface routing

The modem interface can be used in FortiOS as a dedicated interface. Once enabled and configured, you can use it in security policies and define static and dynamic routing. Within the CLI commands for the modem, you can configure the distance and priority of routes involving the modem interface. The CLI commands are:

```
config sysetm modem
    set distance <route_distance>
    set priority <priority_value>
end
```

For more information on the routing configuration in the CLI, see the [CLI Reference](#). For more information on routing and configuring routing, see the [Advanced Routing](#) Guide.

## DHCP servers and relays

Note that DHCP server options are not available in transparent mode.

A DHCP server provides an address to a client on the network, when requested, from a defined address range.

An interface cannot provide both a server and a relay for connections of the same type (regular or IPSec). However, you can configure a Regular DHCP server on an interface only if the interface is a physical interface with a static IP address. You can configure an IPSec DHCP server on an interface that has either a static or a dynamic IP address.

You can configure one or more DHCP servers on any FortiGate interface. A DHCP server dynamically assigns IP addresses to hosts on the network connected to the interface. The host computers must be configured to obtain their IP addresses using DHCP.

If an interface is connected to multiple networks via routers, you can add a DHCP server for each network. The IP range of each DHCP server must match the network address range. The routers must be configured for DHCP relay.

You can configure a FortiGate interface as a DHCP relay. The interface forwards DHCP requests from DHCP clients to an external DHCP server and returns the responses to the DHCP clients. The DHCP server must have appropriate routing so that its response packets to the DHCP clients arrive at the unit.

### DHCP Server configuration

To add a DHCP server, go to *System > Network > Interface*. Edit the interface, and select *Enable* for the *DHCP Server* row.

<b>DHCP Server IP</b>	This appears only when <i>Mode</i> is <i>Relay</i> . Enter the IP address of the DHCP server where the FortiGate unit obtains the requested IP address.
<b>Address Range</b>	By default, the FortiGate unit assigns an address range based on the address of the interface for the complete scope of the address. For example, if the interface address is 172.20.120.230, the default range created is 172.20.120.231 to 172.20.120.254. Select the range and select <i>Edit</i> to adjust the range as needed, or select <i>Create New</i> to add a different range.
<b>Netmask</b>	Enter the netmask of the addresses that the DHCP server assigns.
<b>Default Gateway</b>	Select to either use the same IP as the interface or select <i>Specify</i> and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
<b>DNS Server</b>	Select to use the system's DNS settings or select <i>Specify</i> and enter the IP address of the DNS server.
<b>Advanced</b>	
<b>Mode</b>	Select the type of DHCP server the FortiGate unit will be. By default, it is a server. Select <i>Relay</i> if needed. When <i>Relay</i> is selected, the above configuration is replaced by a field to enter the <i>DHCP Server IP</i> address.

<b>Type</b>	Select to use the DHCP in regular or IPsec mode.
<b>MAC Address Access Control List</b>	<p>Select to match an IP address from the DHCP server to a specific client or device using its MAC address.</p> <p>In a typical situation, an IP address is assigned ad hoc to a client, and that assignment times out after a specific time of inactivity from the client, known as the lease time. To ensure a client or device always has the same IP address, that is, there is no lease time, use IP reservation.</p> <p>For more information, see <a href="#">“Assigning IP address by MAC address” on page 1580</a>.</p>
<b>Add from DHCP Client List</b>	If the client is currently connected and using an IP address from the DHCP server, you can select this option to select the client from the list.

## DHCP in IPv6

You can use DHCP with IPv6 using the CLI. To configure DHCP, ensure IPv6 is enabled by going to *System > Admin > Settings* and enable *IPv6*. Use the CLI command

```
config system dhcp6.
```

For more information on the configuration options, see the [CLI Reference](#).

## Service

On low-end FortiGate units, a DHCP server is configured, by default on the Internal interface:

<b>IP Range</b>	192.168.1.110 to 192.168.1.210
<b>Netmask</b>	255.255.255.0
<b>Default gateway</b>	192.168.1.99
<b>Lease time</b>	7 days
<b>DNS Server 1</b>	192.168.1.99

These settings are appropriate for the default Internal interface IP address of 192.168.1.99. If you change this address to a different network, you need to change the DHCP server settings to match.

Alternatively, after the FortiGate unit assigns an address, you can go to *System > Monitor > DHCP Monitor*, locate the particular user. Select the check box for the user and select *Add to Reserved*.

## Lease time

The lease time determines the length of time an IP address remains assigned to a client. Once the lease expires, the address is released for allocation to the next client request for an IP

address The default lease time is seven days. To change the lease time, use the following CLI commands:

```
config system dhcp server
  edit <server_entry_number>
    set lease-time <seconds>
  end
```

To have an unlimited lease time, set the value to zero.

## DHCP options

When adding a DHCP server, you have the ability to include DHCP codes and options. The DHCP options are BOOTP vendor information fields that provide additional vendor-independent configuration parameters to manage the DHCP server. For example, you may need to configure a FortiGate DHCP server that gives out a separate option as well as an IP address. For example, an environment that needs to support PXE boot with Windows images.

The option numbers and codes are specific to the particular application. The documentation for the application will indicate the values to use. Option codes are represented in a option value/HEX value pairs. The option is a value 1 and 255.

You can add up to three DHCP code/option pairs per DHCP server.

### To configure option 252 with value `http://192.168.1.1/wpad.dat` - CLI

```
config system dhcp server
  edit <server_entry_number>
    set option1 252
      687474703a2f2f3139322e3136382e312e312f777061642e646174
  end
```

For detailed information about DHCP options, see [RFC 2132](#), DHCP Options and BOOTP Vendor Extensions.

## Exclude addresses in DHCP a range

If you have a large address range for the DHCP server, you can block a range of addresses that will not be included in the available addresses for the connecting users. To do this, go to the CLI and enter the commands:

```
config system dhcp server
  edit <server_entry_number>
    config exclude-range
      edit <sequence_number>
        set start-ip <address>
        set end-ip <address>
      end
    end
  end
```

## DHCP Monitor

To view information about DHCP server connections, go to *System > Monitor > DHCP Monitor*. On this page, you can also add IP address to the reserved IP address list.

## Breaking a address lease

Should you need to end an IP address lease, you can break the lease using the CLI. This is useful if you have limited addresses, longer lease times where leases are no longer necessary. For example, with corporate visitors.

**To break a lease enter the CLI command:**

```
execute dhcp lease-clear <ip_address>
```

## Assigning IP address by MAC address

To prevent users in the from changing their IP addresses and causing IP address conflicts or unauthorized use of IP addresses, you can bind an IP address to a specific MAC address using DHCP.

Use the CLI to reserve an IP address for a particular client identified by its device MAC address and type of connection. The DHCP server then always assigns the reserved IP address to the client. The number of reserved addresses that you can define ranges from 10 to 200 depending on the FortiGate model.

After setting up a DHCP server on an interface by going to *System > Network > Interface*, select the blue arrow next to *Advanced* to expand the options. If you know the MAC address of the system select *Create New* to add it, or if the system has already connected, locate it in the list, select its check box and select *Add from DHCP Client List*.

You can also match an address to a MAC address in the CLI. In the example below, the IP address 10.10.10.55 for User1 is assigned to MAC address 00:09:0F:30:CA:4F.

```
config system dhcp reserved-address
  edit User1
    set ip 10.10.10.55
    set mac 00:09:0F:30:CA:4F
    set type regular
  end
```

## DNS services

A DNS server is a public service that converts symbolic node names to IP addresses. A Domain Name System (DNS) server implements the protocol. In simple terms, it acts as a phone book for the Internet. A DNS server matches domain names with the computer IP address. This enables you to use readable locations, such as fortinet.com when browsing the Internet. FortiOS supports DNS configuration for both IPv4 and IPv6 addressing.

The FortiGate unit includes default DNS server addresses. However, these should be changed to those provided by your Internet Service Provider. The defaults are DNS proxies and are not as reliable as those from your ISP.

Within FortiOS, there are two DNS configuration options; each provide a specific service, and can work together to provide a complete DNS solution.

## DNS settings

Basic DNS queries are configured on interfaces that connect to the Internet. When a web site is requested, for example, the FortiGate unit will look to the configured DNS servers to provide the IP address to know which server to contact to complete the transaction.

DNS server addresses are configured by going to *System > Network > DNS*. Here you specify the DNS server addresses. Typically, these addresses are supplied by your ISP. An additional option is available if you have local Microsoft domains on the network, by entering a domain name in the *Local Domain Name* field.

In a situation where all three fields are configured, the FortiGate unit will first look to the local domain. If no match is found, a request is sent to the external DNS servers.

If virtual domains are enabled, you create a DNS database in each VDOM. All of the interfaces in a VDOM share the DNS database in that VDOM.

## Additional DNS CLI configuration

Further options are available from the CLI with the command `config system dns`. Within this command you can set the following commands:

- `dns-cache-limit` - enables you to set how many DNS entries are stored in the cache. Entries that remain in the cache provide a quicker response to requests than going out to the Internet to get the same information.
- `dns-cache-ttl` - enables you to set how long entries remain in the cache in seconds, between 60 and 86,400 (24 hours).
- `cache-notfound-responses` - when enabled, any DNS requests that are returned with NOTFOUND can be stored in the cache.
- `source-ip` - enables you to define a dedicated IP address for communications with the DNS server.

## DNS server

You can also create local DNS servers for your network. Depending on your requirements, you can manually maintain your entries (master DNS server), or use it as a jumping point, where the server refers to an outside source (slave DNS server). A local master DNS server works similarly to the DNS server addresses configured in *System > Network > DNS*, but all entries must be added manually. This enables you to add a local DNS server to include specific URL/IP address combinations.

The DNS server options are not visible in the web-based manager by default. To enable the server, go to *System > Admin > Settings* and select *DNS Database*.

While a master DNS server is an easy method of including regularly used addresses to save on going to an outside DNS server, it is not recommended to make it the authoritative DNS server. IP addresses may change, and maintaining any type of list can quickly become labor-intensive.

A FortiGate master DNS server is best set for local services. For example, if your company has a web server on the DMZ that is accessed by internal employees as well as external users, such as customers or remote users. In this situation, the internal users when accessing the site would send a request for `website.example.com`, that would go out to the DNS server on the web, to return an IP address or virtual IP. With an internal DNS, the same site request is resolved internally to the internal web server IP address, minimizing inbound/outbound traffic and access time.

As a slave, DNS server, the FortiGate server refers to an external or alternate source as way to obtain the url/IP combination. This useful if there is a master DNS server for a large company where a list is maintained. Satellite offices can then connect to the master DNS server to obtain the correct addressing.

The DNS server entries does not allow CNAME entries, as per [rfc 1912](#), section 2.4.

### To configure a master DNS server - web-based manager

1. Go to *System > Network > DNS Server*, and select *Create New*.
2. Select the *Type of Master*.
3. Select the *View as Shadow*.
4. The view is the accessibility of the DNS server. Selecting *Public*, external users can access, or use, the DNS server. Selecting *Shadow*, only internal users can use it.
5. Enter the *DNS Zone*, for example, *WebServer*.
6. Enter the domain name for the zone, for example *example.com*.
7. Enter the hostname of the DNS server, for example, *Corporate*.
8. Enter the contact address for the administrator, for example, *admin@example.com*.
9. Set *Authoritative* to *Disable*.
10. Select *OK*.
11. Enter the DNS entries for the server by selecting *Create New*.
12. Select the *Type*, for example, *Address (A)*.
13. Enter the *Hostname*, for example *web.example.com*.
14. Enter the remaining information, which varies depending on the *Type* selected.
15. Select *OK*.

### To configure a DNS server - CLI

```
config system dns-database
  edit WebServer
    set domain example.com
    set type master
    set view shadow
    set ttl 86400
    set primary-name corporate
    set contact admin@example.com
    set authoritative disable
    config dns-entry
      edit 1
        set hostname web.example.com
        set type A
        set ip 192.168.21.12
        set status enable
      end
    end
  end
end
```

## Recursive DNS

You can set an option to ensure these types of DNS server is not the authoritative server. When configured, the FortiGate unit will check its internal DNS server (Master or Slave). If the request cannot be fulfilled, it will look to the external DNS servers. This is known as a split DNS configuration.

You can also have the FortiGate unit look to an internal server should the Master or Slave not fulfill the request by using the CLI commands:

```
config system dns-database
  edit example.com
    ...
    set view shadow
end
```

For this behavior to work completely, for the external port, you must set the DNS query for the external interface to be recursive. This option is configured in the CLI only.

#### To set the DNS query

```
config system dns-server
  edit wan1
    set mode recursive
end
```

## Dynamic DNS

If your ISP changes the your external IP address on a regular basis, and you have a static domain name, you can configure the external interface to use a dynamic DNS service to ensure external users and/or customers can always connect to your company firewall.

If you have a FortiGuard subscription, you can use FortiGuard as your DDNS server. To configure dynamic DNS in the web-based manager, go to *System > Network > DNS*, select *Enable FortiGuard DDNS*, and enter the relevant information for the interface communicating to the server, and which server to use, and relevant information.

If you do not have a FortiGuard subscription, or want to use an alternate server, you can configure dynamic DNS in the CLI use the commands below. Within the CLI you can configure a DDNS for each interface. Only the first configured port appears in the web-based manager. Additional commands vary with the DDNS server you select.

```
config system ddns
  edit <instance_value>
    set monitor-interface <external_interface>
    set ddns-server <ddns_server_selection>
end
```

You can also use FortiGuard (when subscribed) as a DDNS as well. To configure, use the CLI commands:

```
config system fortiguard
  set ddns-server-ip
  set ddns-server-port
end
```

## FortiClient discovery and registration

FortiOS provides a means of allowing users running FortiClient Endpoint Control software to connect to specific interfaces when connecting to the FortiGate unit. As well as ensuring that remote or local users have FortiClient Endpoint Control software installed on their PC or mobile device.

## FortiClient discovery

You can configure a FortiGate interface as an interface that will accept FortiClient connections. When configured, the FortiGate unit sends broadcast messages which the FortiClient software running on a end user PC is listening for.

### To enable the broadcast message

1. Go to *System > Network > Interface*.
2. Edit the interface to send the broadcast messages.
3. Select *FCT-Access*.
4. In *Device Management*, select *Broadcast Discovery Messages*.
5. Select *OK*.

Once enabled, the FortiGate unit broadcasts a discovery message that includes the IP address of the interface and listening port number to the local network. All PCs running FortiClient on that network listen for this discovery message.

You also have the option of including a registration key. When the FortiClient discovers the FortiGate unit, it is prompted to enter a registration key, defined by the administrator.

### To add a registration key

1. Go to *System > Config > Advanced*.
2. Select *Enable Registration Key for FortiClient*, and enter the key.
3. Select *Apply*.

Ensure you distribute the key to the users that need to connect to the FortiGate unit.

## FortiClient Registration

On the end user side, if FortiClient has not been registered with the FortiGate unit, it is continually listening for the FortiGate discovery message. When this message is detected the un-registered client will pop-up a FortiGate Detected message. The user can choose to either register or ignore the message.

Clients that have registered with that FortiGate unit will not be listening for these messages and will not display the message again.

If you enabled the registration key, the user is prompted to enter the key before a connection can be completed.

For more information on FortiGate registration, see the [FortiClient Administration Guide](#).

## IP addresses for self-originated traffic

On the FortiGate unit, there are a number of protocols and traffic that is specific to the internal workings of FortiOS. For many of these traffic sources, you can identify a specific port/IP

address for this self-originating traffic. The following traffic can be configured to a specific port/IP address:

- SNMP
- Syslog
- alert email
- FortiManager connection IP
- FortiGuard services
- FortiAnalyzer logging
- NTP
- DNS
- Authorization requests such as RADIUS
- FSAE

Configuration of these services is performed in the CLI. In each instance, there is a command `set source-ip`. For example, to set the source IP of NTP to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config system ntp
    set ntpsyn enable
    set syncinterval 5
    set source-ip 192.168.4.5
end
```

To see which services are configured with source-ip settings, use the `get` command:

```
get system source-ip status
```

The output will appear similar to the sample below:

```
NTP: x.x.x.x
DNS: x.x.x.x
SNMP: x.x.x.x
Central Management: x.x.x.x
FortiGuard Updates (AV/IPS): x.x.x.x
FortiGuard Queries (WebFilter/SpamFilter): x.x.x.x
```

## Administration for schools

For system administrator in the school system it is particularly difficult to maintain a network and access to the Internet. There are potential legal liabilities if content is not properly filtered and children are allowed to view pornography and other non-productive and potentially dangerous content. For a school, too much filtering is better than too little. This section describes some basic practices administrators can employ to help maintain control without being too draconian for access to the internet.

### Security policies

The default security policies in FortiOS allow all traffic on all ports and all IP addresses. Not the most secure. While applying UTM profiles can help to block viruses, detect attacks and prevent spam, this doesn't provide a solid overall security option. The best approach is a layered approach; the first layer being the security policy.

When creating outbound security policies, you need to know the answer to the question “What are the students allowed to do?” The answer is surf the web, connect to FTP sites, send/receive email, and so on.

Once you know what the students need to do, you can research the software used and determine the ports the applications use. For example, if the students only require web surfing, then there are only two ports (80 - HTTP and 443 - HTTPS) needed to complete their tasks. Setting the security policies to only allow traffic through two ports (rather than all 65,000), this will significantly lower any possible exploits. By restricting the ports to known services, means stopping the use of proxy servers, as many of them operate on a non-standard port to hide their traffic from URL filtering or HTTP inspection.

## DNS

Students should not be allowed to use whatever DNS they want. This opens another port for them to use and potentially smuggle traffic on. The best approach is to point to an internal DNS server and only allow those devices out on port 53. It's the same approach one would use for SMTP. Only allow the mail server to use port 25 since nothing else should be sending email.

If there is no internal DNS server, then the list of allowed DNS servers they can use should be restrictive. One possible exploit would be for them to set up their own DNS server at home that serves different IPs for known hosts, such as having Google.com sent back the IP for playboy.com.

## Encrypted traffic (HTTPS)

Generally speaking, students should not be allowed to access encrypted web sites. Encrypted traffic cannot be sniffed, and therefore, cannot be monitored. HTTPS traffic should only be allowed when necessary. Most web sites a student needs to access are HTTP, not HTTPS. Due to the nature of HTTPS protocol, and the fact that encryption is an inherent security risk to your network, its use should be restricted.

Adding a security policy that encompasses a list of allowed secure sites will ensure that any HTTPS sites that are required are the only sites a student can go to.

## FTP

For the most part, students should not be using FTP. FTP is not HTTP or HTTPS so you cannot use URL filtering to restrict where they go. This can be controlled with destination IPs in the security policy. With a policy that specifically outlines which FTP addresses are allowed, all other will be blocked.

## Example security policies

Given these requirements, an example set of security policies could look like the following illustration. In a large setup, all the IPs for the students are treated by one of these four policies.

**Figure 247:**Simple security policy setup

<input type="checkbox"/>	Seq. No.	ID	Source	Destination	Schedule	Service	Action	Status
<input type="checkbox"/>	1	2	Student PCs	Allowed Websites	always	HTTPS		
<input type="checkbox"/>	2	3	Student PCs	all	always	HTTP		
<input type="checkbox"/>	3	4	Student PCs	Allowed DNS	always	DNS		
<input type="checkbox"/>	4	5	Student PCs	Allowed FTP	always	FTP		
<input type="checkbox"/>	5		all	all	always	ANY		Implicit

The last policy in the list, included by default, is a deny policy. This adds to the potential of error that could end up allowing unwanted traffic to pass. The deny policy ensures that any traffic making it to this point is stopped. It can also help in further troubleshooting by viewing the logs for denied traffic.

With these policies in place, even before packet inspection occurs, the FortiGate, and the network are fairly secure. Should any of the UTM profiles fail, there is still a basic level of security.

## UTM security profiles

### Antivirus profiles

Antivirus screening should be enabled for any service you have enabled in the security policies. In the case above, HTTP, FTP, as well as POP3 and SMTP (assuming there is email access for students). There is not a virus scan option for HTTPS, because the content is encrypted. Generally speaking, most of the network traffic will be students surfing the web.

To configure antivirus profiles in the web-based manager, go to *UTM Security Profiles > Antivirus > Profile*, or use the CLI commands under `config antivirus profile`.

### Web filtering

The actual filtering of URLs - sites and content - should be performed by FortiGuard. It is easier and web sites are constantly being monitored, and new ones reviewed and added to the FortiGuard databases every day. The FortiGuard categories provide an extensive list of offensive, and non-productive sites.

As well, there are additional settings to include in a web filtering profile to best contain a student's web browsing.

- Web URL filtering should be enabled to set up exemptions for web sites that are blocked or reasons other than category filtering. It also prevents the use of IP addresses to get around web filtering.
- Block invalid URLs - HTTPS only. This option inspects the HTTPS certificate and looks at the URL to ensure it's valid. It is common for proxy sites to create an HTTPS certificate with a garbage URL. If the site is legitimate, it should be set up correctly. If the site approach to security is to ignore it, then their security policy puts your network at risk and the site should be blocked.

Web filtering options are configured in the web-based manager by going to *UTM Security Profiles > Web filter > Profile*, or in the CLI under `config webfilter profile`.

### Advanced options

There are a few Advanced options to consider for a web filtering profile:

- Enable *Provide details for blocked HTTP 4xx and 5xx errors*. Under normal circumstances there are exploits that can be used with 400 and 500 series messages to access the web

site. While most students probably won't know how to do this, there is no harm in being cautious. It only takes one.

- Enable *Rate Images by URL*. This option only works with Google images. It examines the URL that the image is stored at to get a rating on it, then blocks or allows the image based on the rating of the originating URL. It does not inspect the image contents. Most image search engines to a perfect and pass the images directly to the browser.
- Enable *Block HTTP redirects by rating*. An HTTP redirect is one method of getting around ratings. Go to one web site that has an allowed rating, and it redirects to another web site that may want blocked.

## Categories and Classifications

For the selection of what FortiGuard categories and classifications that should be blocked, that is purely based on the school system and its Internet information policy.

## Email Filtering

Other than specific teacher-led email inboxes, there is no reason why a student should be able to access, read or send personal email. Ports for POP3, SMTP and IMAP should not be opened in a security policies.

## IPS

The intrusion protection profiles should be used to ensure the student PCs are not vulnerable to attacks, nor do you want students making attacks. As well, IPS can do more than simple vulnerability scans. With a FortiGuard subscription, IPS signatures are pushed to the FortiGate unit. New signatures are released constantly for various intrusions as they are discovered.

FortiOS includes a number of predefined IPS sensors that you can enable by default. Selecting the all\_default signature is a good place to start as it includes the major signatures.

To configure IPS sensors in the web-based manager, go to *UTM Security Profiles > Intrusion Protection > IPS Sensor*, on the CLI use commands under `config ips sensor`.

## Application control

Application control uses IPS signatures to limit the use of instant messaging and peer-to-peer applications which can lead to possible infections on a student's PC. FortiOS includes a number of pre-defined application categories. To configure and maintain application control profiles in the web-based manager, go to *UTM Security Profiles > Application Control > Application Sensor*. In the CLI use commands under `config application list`.

Some applications to consider include proxies, botnets, toolbars and P2P applications.

## Logging

Turn on all logging - every option in this section should be enabled. This is not where you decide what you are going to log. It is simply defining what the UTM profiles can log.

Logging everything is a way to monitor traffic on the network, see what student's are utilizing the most, and locate any potential holes in your security plan. As well, keeping this information may help to prove negligence later in necessary.

## Tag management

Tag management provide a method of categorizing, or labelling objects within FortiOS using keywords. You can give the following elements a “tag”, similar to a keyword:

- IPS signature
- application signature
- security policy
- firewall address

Tagging is way to organize the various elements, especially if you have a large number of addresses, security policies to manage and keep track of. Tagging enables you to break these elements into groups, but each element can belong to more than one group. Tags help you find elements which have something in common, be it a group, user or location. This is very similar to tagging found on photo sharing sites.

To use tagging, you need to enable it for 1U FortiGate units. It is enabled by default on all 2U FortiGate units and blades.

### To enable tagging - web-based manager

1. Go to *System > Admin > Settings*.
2. Select *Object Tagging and Coloring*.
3. Select *Apply*.

### To enable tagging - CLI

```
config system global
    set gui-object-tags enable
end
```

## Adding and removing tags

You add and remove tags when you create the various elements. For example, when adding a firewall address, a section below the Interface selection enables you to add tags for that element, such as the department, region, or really, anything to help identify the element. When editing, applied tags appear as well. To add a tag, right-click on the element you want to add a tag to.

**Figure 248:**Adding tags to a new address.

The screenshot shows the 'New Address' configuration window. It has a title bar 'New Address'. Below it, there are several fields: 'Address Name' with the value 'User\_1', 'Color' with a '[Change]' button, 'Type' with a dropdown menu showing 'Subnet / IP Range', 'Subnet / IP Range' with the value '172.20.120.12', 'Interface' with a dropdown menu showing 'dmz2', and 'Tags'. Under 'Tags', there is a section 'Applied tags' showing 'accounting' with a close button. Below that, there is an 'Add tags' section with the text 'west coast' and a plus button. At the bottom right, there are 'OK' and 'Cancel' buttons.

To remove a tag, in the element, click the tag in the Applied Tags list.

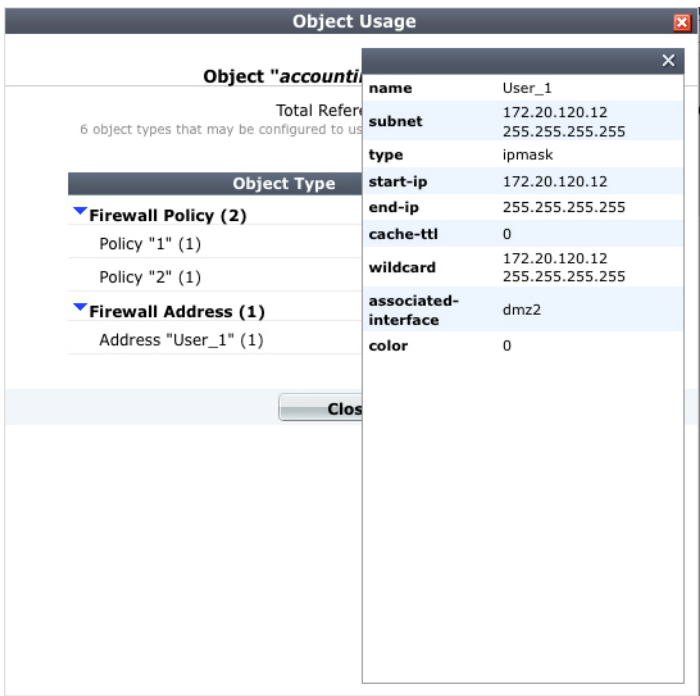

## Reviewing tags

Tags can be reviewed in one location by going to *System > Config > Tag Management*. In this screen, all tags used appear. The visual size of the tag name indicates the usage; the bigger the size, the more it is used. By hovering over the keyword, a fly out indicates how many times it has been used.

To see where it was used, click the keyword. An *Object Usage* window displays all the reference categories where the keyword was used, and the number of times. Selecting the expand arrow further details its use.

Further, for security policies for example, you can select the *View* icon and see the details of the particular element. If need be, select the *Edit* icon to modify the element.

**Figure 249:**Viewing the address information for a tagged object

## Tagging guidelines

Given the ease that tags can be added to elements in FortiOS, it makes sense to jump right in and begin applying tags to elements and object. However, this type of methodology will lead to problems down the road as new elements are added.

A methodology should be considered and developed before applying tags. This doesn't mean you need to develop an entire thesaurus or reference guide for all possibilities of tags. However, taking some time to develop a methodology for the keywords you intend to use will benefit later when new security policies, addresses, and so on are added. Some things to consider when developing a tag list:

- the hierarchy used for the organization such as region, city location, building location
- department names and if short forms or long forms are used
- will acronyms be used or terms spelled out.
- how granular will the tagging be

As tags are added, previously used tags appear so there is an opportunity to use previously used tags. However, you want to avoid a situation where both accounting and acct are both

options. This is also important if there are multiple administrators in different locations to ensure consistency.

At any time, you can change or even remove tags. It is best to do a bit of planning ahead of time to avoid unnecessary work later on.

## Replacement messages list

The replacement message list in *System > Config > Replacement Messages*.

The replacement messages list enables you to view and customize replacement messages. Use the expand arrow beside each type to display the replacement messages for that category. Select the *Edit* icon beside each replacement message to customize that message for your requirements.

Should you make a major error to the code, you can select the *Restore Default* to return to the original message and code base.

If you are viewing the replacement messages list in a VDOM, any messages that have been customized for that VDOM are displayed with a Reset icon that you can use to reset the replacement message to the global version.

For connections requiring authentication, the FortiGate unit uses HTTP to send an authentication disclaimer page for the user to accept before a security policy is in effect. Therefore, the user must initiate HTTP traffic first in order to trigger the authentication disclaimer page. Once the disclaimer is accepted, the user can send whatever traffic is allowed by the security policy.

## Replacement message images

You can add images to replacement messages to:

- disclaimer pages
- login pages
- declined disclaimer pages
- login failed page
- login challenge pages
- keepalive pages

Image embedding is also available to the endpoint NAC download portal and recommendation portal replacement messages, as well as HTTP replacement messages.

Supported image formats are GIF, JPEG, TIFF and PNG. The maximum file size supported is 6000 bytes.

## Adding images to replacement messages

### To upload an image for use in a message

1. Go to *System > Config > Replacement Messages*.
2. Select *Manage Images* at the top of the page.
3. Select *Create New*.
4. Enter a *Name* for the image.
5. Select the *Content Type*.
6. Select *Browse* to locate the file and select *OK*.

The image that you include in a replacement message, must have the following html:

```
<img src=%%IMAGE: <config_image_name>%% size=<bytes> >
```

For example:

```
<img src=%%IMAGE: logo_hq%% size=4272>
```

## Modifying replacement messages

Replacement messages can be modified to include a message or content that suits your organization.

Use the expand arrows to view the replacement message list for a given category. Messages are in HTML format. For descriptions of the replacement message tags, see [Replacement message tags](#).

To change a replacement message, go to *System > Config > Replacement Messages* select the replacement message that you want to modify. At the bottom pane of the window, you can the message on one side and the HTML code on the other side. The message view changes in real-time as you change the content.

A list of common replacement messages appears in the main window. To see the entire list and all categories of replacement messages, in the upper-right corner of the window, select *Extended View*.

## Replacement message tags

Replacement messages can include replacement message tags, or variables. When users receive the message, the message tag is replaced with content relevant to the message. The table lists the replacement message tags that you can use.

**Table 70:** Replacement message tags

Tag	Description
%%AUTH_LOGOUT%%	The URL that will immediately delete the current policy and close the session. Used on the auth-keepalive page.
%%AUTH_REDIR_URL%%	The auth-keepalive page can prompt the user to open a new window which links to this tag.
%%CATEGORY%%	The name of the content category of the web site.
%%DEST_IP%%	The IP address of the request destination from which a virus was received. For email this is the IP address of the email server that sent the email containing the virus. This tag only works with alert email replacement messages.
%%DURATION%% (FortiOS Carrier only)	The amount of time in the reporting period. This is user defined in the protection profile.
%%EMAIL_FROM%%	The email address of the sender of the message from which the file was removed.
%%EMAIL_TO%%	The email address of the intended receiver of the message from which the file was removed.
%%FAILED_MESSAGE%%	The failed to login message displayed on the auth-login-failed page.

**Table 70:** Replacement message tags (continued)

Tag	Description
%%FILE%%	The name of a file that has been removed from a content stream. This could be a file that contained a virus or was blocked by antivirus file blocking. %%FILE%% can be used in virus and file block messages.
%%FORTIGUARD_WF%%	The FortiGuard - Web Filtering logo.
%%FORTINET%%	The Fortinet logo.
%%LINK%%	The link to the FortiClient Host Security installs download for the Endpoint Control feature.
%%HTTP_ERR_CODE%%	The HTTP error code. "404" for example.
%%HTTP_ERR_DESC%%	The HTTP error description.
%%KEEPALIVEURL%% (FortiOS Carrier only)	auth-keepalive-page automatically connects to this URL every %%TIMEOUT%% seconds to renew the connection policy.
%%MMS_SENDER%% (FortiOS Carrier only)	Senders MSISDN from message header.
%%MMS_RECIPIENT%% (FortiOS Carrier only)	Recipients MSISDN from message header.
%%MMS_SUBJECT%% (FortiOS Carrier only)	MMS Subject line to help with message identity.
%%MMS_HASH_CHECKSUM%%	Value derived from hash calculation - will only be shown on duplicate message alerts.
%%MMS_THRESH%%	Mass MMS alert threshold that triggered this alert.
%%NIDSEVENT%%	The IPS attack message. %%NIDSEVENT%% is added to alert email intrusion messages.
%%NUM_MSG%% (FortiOS Carrier only)	The number of time the device tried to send the message with banned content within the reporting period.
%%OVERRIDE%%	The link to the FortiGuard Web Filtering override form. This is visible only if the user belongs to a group that is permitted to create FortiGuard web filtering overrides.
%%OVRD_FORM%%	The FortiGuard web filter block override form. This tag must be present in the FortiGuard Web Filtering override form and should not be used in other replacement messages.

**Table 70:** Replacement message tags (continued)

Tag	Description
%%PROTOCOL%%	The protocol (http, ftp, pop3, imap, or smtp) in which a virus was detected. %%PROTOCOL%% is added to alert email virus messages.
%%QUARFILENAME%%	The name of a file that has been removed from a content stream and added to the quarantine. This could be a file that contained a virus or was blocked by antivirus file blocking. %%QUARFILENAME%% can be used in virus and file block messages. Quarantining is only available on FortiGate units with a local disk.
%%QUOTA_INFO%%	Display information about the traffic shaping quota setting that is blocking the user. Used in traffic quota control replacement messages.
%%QUESTION%%	Authentication challenge question on auth-challenge page. Prompt to enter username and password on auth-login page.
%%SERVICE%%	The name of the web filtering service.
%%SOURCE_IP%%	The IP address of the request originator who would have received the blocked file. For email this is the IP address of the user's computer that attempted to download the message from which the file was removed. This tag only works with alert email replacement messages.
%%TIMEOUT%%	Configured number of seconds between authentication keepalive connections. Used on the auth-keepalive page.
%%URL%%	The URL of a web page. This can be a web page that is blocked by web filter content or URL blocking. %%URL%% can also be used in http virus and file block messages to be the URL of the web page from which a user attempted to download a file that is blocked.
%%VIRUS%%	The name of a virus that was found in a file by the antivirus system. %%VIRUS%% can be used in virus messages

## Administration replacement message

If you enter the following CLI command the FortiGate unit displays the *Administration Login Disclaimer* whenever an administrator logs into the FortiGate unit's web-based manager or CLI.

```
config system global
    set access-banner enable
end
```

The web-based manager administrator login disclaimer contains the text of the Login Disclaimer replacement message as well as Accept and Decline buttons. The administrator must select accept to login.

## Alert Mail replacement messages

The FortiGate unit adds the alert mail replacement messages listed in the following table to alert email messages sent to administrators. If you enable the option *Send alert email for logs based on severity*, whether or not replacement messages are sent by alert email depends on how you set the alert email in *Minimum log level*.

## Authentication replacement messages

The FortiGate unit uses the text of the authentication replacement messages for various user authentication HTML pages that are displayed when a user is required to authenticate because a security policy includes at least one identity-based policy that requires firewall users to authenticate.

These replacement message pages are for authentication using HTTP and HTTPS. You cannot customize the firewall authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

Users see the authentication login page when they use a VPN or a security policy that requires authentication. You can customize this page in the same way as you modify other replacement messages.

There are some unique requirements for these replacement messages:

- The login page must be an HTML page containing a form with ACTION="/" and METHOD="POST"
- The form must contain the following hidden controls:
  - `<INPUT TYPE="hidden" NAME="%%MAGICID%%" VALUE="%%MAGICVAL%%">`
  - `<INPUT TYPE="hidden" NAME="%%STATEID%%" VALUE="%%STATEVAL%%">`
  - `<INPUT TYPE="hidden" NAME="%%REDIRID%%" VALUE="%%PROTURI%%">`
- The form must contain the following visible controls:
  - `<INPUT TYPE="text" NAME="%%USERNAMEID%%" size=25>`
  - `<INPUT TYPE="password" NAME="%%PASSWORDID%%" size=25>`

### Example

The following is an example of a simple authentication page that meets the requirements listed above.

```
<HTML><HEAD><TITLE>Firewall Authentication</TITLE></HEAD>
  <BODY><H4>You must authenticate to use this service.</H4>
<FORM ACTION="/" method="post">
  <INPUT NAME="%%MAGICID%%" VALUE="%%MAGICVAL%%" TYPE="hidden">
<TABLE ALIGN="center" BGCOLOR="#00cccc" BORDER="0"
  CELLPADDING="15" CELLSPACING="0" WIDTH="320"><TBODY>
<TR><TH>Username:</TH>
  <TD><INPUT NAME="%%USERNAMEID%%" SIZE="25" TYPE="text"> </TD></TR>
<TR><TH>Password:</TH>
  <TD><INPUT NAME="%%PASSWORDID%%" SIZE="25" TYPE="password">
  </TD></TR>
<TR><TD COLSPAN="2" ALIGN="center" BGCOLOR="#00cccc">
  <INPUT NAME="%%STATEID%%" VALUE="%%STATEVAL%%" TYPE="hidden">
```

```

        <INPUT NAME="%%REDIRID%%" VALUE="%%PROTURI%%" TYPE="hidden">
        <INPUT VALUE="Continue" TYPE="submit"> </TD></TR>
</TBODY></TABLE></FORM></BODY></HTML>

```

## Captive Portal Default replacement messages

The Captive Portal Default replacement messages are used for wireless authentication only. You must have a VAP interface with the security set as captive portal to trigger these replacement messages.

## Device Detection Portal replacement message

The FortiGate unit displays the replacement message when the FortiGate unit cannot determine the type of BYOD or handheld device is used to connect the network.

## Email replacement messages

The FortiGate unit sends the mail replacement messages to email clients using IMAP, POP3, or SMTP when an event occurs such as antivirus blocking a file attached to an email that contains a virus. Email replacement messages are text messages.

If the FortiGate unit supports SSL content scanning and inspection these replacement messages can also be added to IMAPS, POP3S, and SMTPS email messages.

## Endpoint Control replacement message

The FortiGate unit displays the replacement message when the FortiClient Endpoint Security software is not installed or registered correctly with the FortiGate unit.

## FTP replacement messages

The FortiGate unit sends the FTP replacement messages listed in the table below to FTP clients when an event occurs such as antivirus blocking a file that contains a virus in an FTP session. FTP replacement messages are text messages.

## FortiGuard Web Filtering replacement messages

The FortiGate unit sends the FortiGuard Web Filtering replacement messages listed in the table to web browsers using the HTTP protocol when FortiGuard web filtering blocks a URL, provides details about blocked HTTP 4xx and 5xx errors, and for FortiGuard overrides. FortiGuard Web Filtering replacement messages are HTTP pages.

If the FortiGate unit supports SSL content scanning and inspection and if *Protocol Recognition > HTTPS Content Filtering Mode* is set to Deep Scan in the antivirus profile, these replacement messages can also replace web pages downloaded using the HTTPS protocol.

## HTTP replacement messages

The FortiGate unit sends the HTTP replacement messages listed in the following table to web browsers using the HTTP protocol when an event occurs such as antivirus blocking a file that contains a virus in an HTTP session. HTTP replacement messages are HTML pages.

If the FortiGate unit supports SSL content scanning and inspection, and if under HTTPS in the protocol option list has Enable Deep Scan enabled, these replacement messages can also replace web pages downloaded using the HTTPS protocol.

## IM replacement messages

The FortiGate unit sends the IM replacement messages listed in to IM clients using AIM, ICQ, MSN, or Yahoo! Messenger when an event occurs such as antivirus blocking a file attached to an email that contains a virus. IM replacement messages are text messages.

## NNTP replacement messages

The FortiGate unit sends the NNTP replacement messages listed in the following table to NNTP clients when an event occurs such as antivirus blocking a file attached to an NNTP message that contains a virus. NNTP replacement messages are text messages.

## Spam replacement messages

The FortiGate unit adds the Spam replacement messages listed in the following table to SMTP server responses if the email message is identified as spam and the spam action is discard. If the FortiGate unit supports SSL content scanning and inspection these replacement messages can also be added to SMTPS server responses.

## NAC quarantine replacement messages

The page that is displayed for the user depends on whether NAC quarantine blocked the user because a virus was found, a DoS sensor detected an attack, an IPS sensor detected an attack, or a DLP rule with action set to *Quarantine IP address* or *Quarantine Interface* matched a session from the user.

The default messages inform the user of why they are seeing this page and recommend they contact the system administrator. You can customize the pages as required, for example to include an email address or other contact information or if applicable a note about how long the user can expect to be blocked.

## SSL VPN replacement message

The SSL VPN login replacement message is an HTML replacement message that formats the FortiGate SSL VPN portal login page. You can customize this replacement message according to your organization's needs. The page is linked to FortiGate functionality and you must construct it according to the following guidelines to ensure that it will work.

- The login page must be an HTML page containing a form with ACTION="%%SSL\_ACT%%" and METHOD="%%SSL\_METHOD%%"
- The form must contain the %%SSL\_LOGIN%% tag to provide the login form.
- The form must contain the %%SSL\_HIDDEN%% tag.

## Web Proxy replacement messages

The FortiGate unit sends Web Proxy replacement messages listed in the table below when a web proxy event occurs that is detected and matches the web proxy configuration. These replacement messages are web pages that appear within your web browser.

The following web proxy replacement messages require an identity-based security policy so that the web proxy is successful. You can also enable FTP-over-HTTP by selecting the *FTP* option in *System > Network > Explicit Proxy*.

## Traffic quota control replacement messages

When user traffic is going through the FortiGate unit and it is blocked by traffic shaping quota controls, users see the *Traffic shaper block message* or the *Per IP traffic shaper block message* when they attempt to connect through the FortiGate unit using HTTP.

The traffic quota HTTP pages should contain the `%%QUOTA_INFO%%` tag to display information about the traffic shaping quota setting that is blocking the user.

## MM1 replacement messages

MM1 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

You must have *Remove Blocked* selected within the MMS profile if you want to remove the content that is intercepted during MMS scanning on the FortiGate unit.

## MM3 replacement messages

MM3 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

You must have *Remove Blocked* selected within the MMS profile if you want to remove the content that is intercepted during MMS scanning on the unit.

## MM4 replacement messages

MM4 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

## MM7 replacement messages

MM7 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

## MMS replacement messages

The MMS replacement message is sent when a section of an MMS message has been replaced because it contains a blocked file. This replacement message is in HTML format.

The message text is:

```
<HTML><BODY>This section of the message has been replaced because it  
contained a blocked file</BODY></HTML>
```

## Replacement message groups

Replacement message groups enable you to view common messages in groups for large carriers. To view grouped replacement messages, go to *System > Admin > Settings* and select *Replacement Message Groups* in the *Display Options on GUI* section.

Message groups can be configured by going to *Config > Replacement Message Group*.

Using the defined groups, you can manage specific replacement messages from a single location, rather than searching through the entire replacement message list.

If you enable virtual domains (VDOMs) on the FortiGate unit, replacement message groups are configured separately for each virtual domain. Each virtual domain has its own default

replacement message group, configured from *System > Config > Replacement Messages Group*.

When you modify a message in a replacement message group, a Reset icon appears beside the message in the group. You can select this Reset icon to reset the message in the replacement message group to the default version.

All MM1/4/7 notification messages for FortiOS Carrier (and MM1 retrieve-conf messages) can contain a SMIL layer and all MM4 notification messages can contain an HTML layer in the message. These layers can be used to brand messages by using logos uploaded to the FortiGate unit via the 'Manage Images' link found on the replacement message group configuration page.

## Disk

To view the status and storage information of the local disk on your FortiGate unit, go to *System > Config > Advanced*. The *Disk* menu appears only on FortiGate units with an internal hard or flash disk.

### Formatting the disk

The internal disk of the FortiGate unit (if available) can be formatted by going to *System > Config > Disk* and selecting *Format*.

Formatting the disk will erase all data on it, including databases for antivirus and IPS; logs, quarantine files, and WAN optimization caches. The FortiGate unit requires a reboot once the disk has been formatted.

### Setting space quotas

If the FortiGate unit has an internal hard or flash disk, you can allocate the space on the disk for specific logging and archiving, and WAN optimization. By default, the space is used on an as required basis. As such, a disk can fill up with basic disk logging, leaving less potential space for quarantine.

By going to *System > Config > Disk*, you can select the *Edit* icon for *Logging and Archiving* and *WAN Optimization & Web Cache* and define the amount of space each log, archive and WAN optimization has on the disk.

## CLI Scripts

To upload bulk CLI commands and scripts, go to *System > Config > Advanced*.

Scripts are text files containing CLI command sequences. Scripts can be used to deploy identical configurations to many devices. For example, if all of your devices use identical security policies, you can enter the commands required to create the security policies in a script, and then deploy the script to all the devices which should use those same settings.

Use a text editor such as Notepad or other application that creates simple text files. Enter the commands in sequence, with each line as one command, similar to examples throughout the FortiOS documentation set.

If you are using a FortiGate unit that is not remotely managed by a FortiManager unit or the FortiGuard Analysis and Management Service, the scripts you upload are executed and discarded. If you want to execute a script more than once, you must keep a copy on your management PC.

If your FortiGate unit is configured to use a FortiManager unit, you can upload your scripts to the FortiManager unit, and run them from any FortiGate unit configured to use the FortiManager unit. If you upload a script directly to a FortiGate unit, it is executed and discarded.

If your FortiGate unit is configured to use FortiGuard Analysis and Management Service, scripts you upload are executed and stored. You can run uploaded scripts from any FortiGate unit configured with your FortiGuard Analysis and Management Service account. The uploaded script files appear on the FortiGuard Analysis and Management Service portal web site.

## Uploading script files

After you have created a script file, you can then upload it through *System > Config > Advanced*. When a script is uploaded, it is automatically executed.

Commands that require the FortiGate unit to reboot when entered in the command line will also force a reboot if included in a script.

### To execute a script

1. Go to *System > Config > Advanced*.
2. Verify that *Upload Bulk CLI Command File* is selected.
3. Select *Browse* to locate the script file.
4. Select *Apply*.

If the FortiGate unit is not configured for remote management, or if it is configured to use a FortiManager unit, uploaded scripts are discarded after execution. Save script files to your management PC if you want to execute them again later.

If the FortiGate unit is configured to use the FortiGuard Analysis and Management Service, the script file is saved to the remote server for later reuse. You can view the script or run it from the FortiGuard Analysis and Management Service portal web site.

## Rejecting PING requests

The factory default configuration of your FortiGate unit allows the default external interface to respond to ping requests. Depending on the model of your FortiGate unit the actual name of this interface will vary. For the most secure operation, you should change the configuration of the external interface so that it does not respond to ping requests. Not responding to ping requests makes it more difficult for a potential attacker to detect your FortiGate unit from the Internet. One such potential threat are Denial of Service (DoS) attacks.

A FortiGate unit responds to ping requests if ping administrative access is enabled for that interface.

### To disable ping administrative access - web-based manager

1. Go to *System > Network > Interface*.
2. Choose the external interface and select *Edit*.
3. Clear the *Ping Administrative Access* check box.
4. Select *OK*.

In the CLI, when setting the `allowaccess` settings, by selecting the access types and not including the PING option, that option is then not selected. In this example, only HTTPS is selected.

### To disable ping administrative access - CLI

```
config system interface
  edit external
    set allowaccess https
  end
```

## Opening TCP 113

Although seemingly contrary to conventional wisdom of closing ports from hackers, this port, which is used for ident requests, should be opened.

Port 113 initially was used as an authentication port, and later defined as an identification port (see RFC 1413). Some servers may still use this port to help in identifying users or other servers and establish a connection. Because port 113 receives a lot of unsolicited traffic, many routers, including on the FortiGate unit, close this port.

The issue arises in that unsolicited requests are stopped by the FortiGate unit, which will send a response saying that the port is closed. In doing so, it also lets the requesting server know there is a device at the given address, and thus announcing its presence. By enabling traffic on port 113, requests will travel to this port, and will most likely, be ignored and never responded to.

By default, the ident port is closed. To open it, use the following CLI commands:

```
config system interface
  edit <port_name>
    set ident_accept enable
  end
```

You could also further use port forwarding to send the traffic to a non-existent IP address and thus never have a response packet sent.

## Obfuscate HTTP responses

The FortiGate unit can obfuscate the HTTP responses from the FortiGate admin GUI and SSL VPN servers. By default this option is not enabled. To obfuscate HTTP headers, use the following CLI command:

```
config system global
  set http-obfuscate {none | header-only | modified | no-error}
end
```

Where:

none — do not hide the FortiGate web server identity.

header-only — hides the HTTP server banner.

modified — provides modified error responses.

no-error — suppresses error responses.

# Session helpers

The FortiOS firewall can analyze most TCP/IP protocol traffic by comparing packet header information to security policies. This comparison determines whether to accept or deny the packet and the session that the packet belongs to.

Some protocols include information in the packet body (or payload) that must be analyzed to successfully process sessions for this protocol. For example, the SIP VoIP protocol uses TCP control packets with a standard destination port to set up SIP calls. But the packets that carry the actual conversation can use a variety of UDP protocols with a variety of source and destination port numbers. The information about the protocols and port numbers used for a SIP call is contained in the body of the SIP TCP control packets. To successfully process SIP VoIP calls, FortiOS must be able to extract information from the body of the SIP packet and use this information to allow the voice-carrying packets through the firewall.

FortiOS uses session helpers to analyze the data in the packet bodies of some protocols and adjust the firewall to allow those protocols to send packets through the firewall.

This section includes the topics:

- [Viewing the session helper configuration](#)
- [Changing the session helper configuration](#)
- [DCE-RPC session helper \(dcerpc\)](#)
- [DNS session helpers \(dns-tcp and dns-udp\)](#)
- [File transfer protocol \(FTP\) session helper \(ftp\)](#)
- [H.245 session helpers \(h245I and h245O\)](#)
- [H.323 and RAS session helpers \(h323 and ras\)](#)
- [Media Gateway Controller Protocol \(MGCP\) session helper \(mgcp\)](#)
- [ONC-RPC portmapper session helper \(pmap\)](#)
- [PPTP session helper for PPTP traffic \(pptp\)](#)
- [Remote shell session helper \(rsh\)](#)
- [Real-Time Streaming Protocol \(RTSP\) session helper \(rtsp\)](#)
- [Session Initiation Protocol \(SIP\) session helper \(sip\)](#)
- [Trivial File Transfer Protocol \(TFTP\) session helper \(tftp\)](#)
- [Oracle TNS listener session helper \(tns\)](#)

## Viewing the session helper configuration

You can view the session helpers enabled on your FortiGate unit in the CLI using the commands below. The following output shows the first two session helpers. The number of session helpers can vary to around 20.

```
show system session-helper
config system session-helper
edit 1
    set name pptp
    set port 1723
    set protocol 6
```

```

end
next
    set name h323
    set port 1720
    set protocol 6
next
end
.
.

```

The configuration for each session helper includes the name of the session helper and the port and protocol number on which the session helper listens for sessions. Session helpers listed on protocol number 6 (TCP) or 17 (UDP). For a complete list of protocol numbers see: [Assigned Internet Protocol Numbers](#).

For example, the output above shows that FortiOS listens for PPTP packets on TCP port 1723 and H.323 packets on port TCP port 1720.

If a session helper listens on more than one port or protocol the more than one entry for the session helper appears in the `config system session-helper` list. For example, the pmap session helper appears twice because it listens on TCP port 111 and UDP port 111. The rsh session helper appears twice because it listens on TCP ports 514 and 512.

## Changing the session helper configuration

Normally you will not need to change the configuration of the session helpers. However in some cases you may need to change the protocol or port the session helper listens on.

### Changing the protocol or port that a session helper listens on

Most session helpers are configured to listen for their sessions on the port and protocol that they typically use. If your FortiGate unit receives sessions that should be handled by a session helper on a non-standard port or protocol you can use the following procedure to change the port and protocol used by a session helper. The following example shows how to change the port that the pmap session helper listens on for Sun RPC portmapper TCP sessions. By default pmap listens on TCP port 111.

#### To change the port that the pmap session helper listens on to TCP port 112

1. Confirm that the TCP pmap session helper entry is 11 in the session-helper list:

```

show system session-helper 11
config system session-helper
    edit 11
        set name pmap
        set port 111
        set protocol 6
    next
end

```

2. Enter the following command to change the TCP port to 112.

```

config system session-helper
    edit 11
        set port 112
    end

```

3. The pmap session helper also listens on UDP port 111. Confirm that the UDP pmap session helper entry is 12 in the session-helper list:

```
show system session-helper 12
config system session-helper
edit 12
set name pmap
set port 111
set protocol 17
next
end
```

4. Enter the following command to change the UDP port to 112.

```
config system session-helper
edit 12
set port 112
end
end
```

Use the following command to set the h323 session helper to listen for ports on the UDP protocol.

#### **To change the protocol that the h323 session helper listens on**

1. Confirm that the h323 session helper entry is 2 in the session-helper list:

```
show system session-helper 2
config system session-helper
edit 2
set name h323
set port 1720
set protocol 6
next
end
```

2. Enter the following command to change the protocol to UDP.

```
config system session-helper
edit 2
set protocol 17
end
end
```

If a session helper listens on more than one port or protocol, then multiple entries for the session helper must be added to the session helper list, one for each port and protocol combination. For example, the rtsp session helper listens on TCP ports 554, 7070, and 8554 so there are three rtsp entries in the session-helper list. If your FortiGate unit receives rtsp packets on a different TCP port (for example, 6677) you can use the following command to configure the rtsp session helper to listen on TCP port 6677.

#### **To configure a session helper to listen on a new port and protocol**

```
config system session-helper
edit 0
set name rtsp
set port 6677
set protocol 6
end
```

## Disabling a session helper

In some cases you may need to disable a session helper. Disabling a session helper just means removing it from the session-helper list so that the session helper is not listening on a port. You can completely disable a session helper by deleting all of its entries from the session helper list. If there are multiple entries for a session helper on the list you can delete one of the entries to prevent the session helper from listening on that port.

### To disable the mgcp session helper from listening on UDP port 2427

1. Enter the following command to find the mgcp session helper entry that listens on UDP port 2427:

```
show system session-helper
.
.
.
edit 19
    set name mgcp
    set port 2427
    set protocol 17
next
.
.
.
```

2. Enter the following command to delete session-helper list entry number 19 to disable the mgcp session helper from listening on UDP port 2427:

```
config system session-helper
    delete 19
```

By default the mgcp session helper listens on UDP ports 2427 and 2727. The previous procedure shows how to disable the mgcp protocol from listening on port 2427. The following procedure completely disables the mgcp session helper by also disabling it from listening on UDP port 2727.

### To completely disable the mgcp session helper

1. Enter the following command to find the mgcp session helper entry that listens on UDP port 2727:

```
show system session-helper
.
.
.
edit 20
    set name mgcp
    set port 2727
    set protocol 17
next
.
.
.
```

2. Enter the following command to delete session-helper list entry number 20 to disable the mgcp session helper from listening on UDP port 2727:

```
config system session-helper
    delete 20
```

## DCE-RPC session helper (dcerpc)

Distributed Computing Environment Remote Procedure Call (DCE-RPC) provides a way for a program running on one host to call procedures in a program running on another host. DCE-RPC (also called MS RPC for Microsoft RPC) is similar to ONC-RPC. Because of the large number of RPC services, for example, MAPI, the transport address of an RPC service is dynamically negotiated based on the service program's universal unique identifier (UUID). The Endpoint Mapper (EPM) binding protocol in FortiOS maps the specific UUID to a transport address.

To accept DCE-RPC sessions you must add a security policy with service set to any or to the DEC-RPC pre-defined service (which listens on TCP and UDP ports 135). The dcerpc session helper also listens on TCP and UDP ports 135.

The session allows FortiOS to handle DCE-RPC dynamic transport address negotiation and to ensure UUID-based security policy enforcement. You can define a security policy to permit all RPC requests or to permit by specific UUID number.

In addition, because a TCP segment in a DCE-RPC stream might be fragmented, it might not include an intact RPC PDU. This fragmentation occurs in the RPC layer; so FortiOS does not support parsing fragmented packets.

## DNS session helpers (dns-tcp and dns-udp)

FortiOS includes two DNS session helpers, dns-tcp, a session helper for DNS over TCP, and dns-udp, a session helper for DNS over UDP.

To accept DNS sessions you must add a security policy with service set to any or to the DNS pre-defined service (which listens on TCP and UDP ports 53). The dns-udp session helper also listens on UDP port 53. By default the dns-tcp session helper is disabled. If needed you can use the following command to enable the dns-tcp session helper to listen for DNS sessions on TCP port 53:

```
config system session-helper
  edit 0
    set name dns-tcp
    set port 53
    set protocol 6
  end
```

## File transfer protocol (FTP) session helper (ftp)

The FTP session helper monitors PORT, PASV and 227 commands and NATs the IP addresses and port numbers in the body of the FTP packets and opens ports on the FortiGate unit as required.

To accept FTP sessions you must add a security policy with service set to any or to the FTP, FTP\_Put, and FTP\_GET pre-defined services (which all listen on TCP port 21).

## H.245 session helpers (h245I and h245O)

H.245 is a control channel protocol used for H.323 and other similar communication sessions. H.245 sessions transmit non-telephone signals. H.245 sessions carry information needed for multimedia communication, such as encryption, flow control jitter management and others.

FortiOS includes two H.245 sessions helpers, h245I which is for H.245 call in and h245O which is for H.245 call out sessions. There is no standard port for H.245. By default the H.245 sessions helpers are disabled. You can enable them as you would any other session helper. When you enable them, you should specify the port and protocol on which the FortiGate unit receives H.245 sessions.

## **H.323 and RAS session helpers (h323 and ras)**

The H.323 session helper supports secure H.323 voice over IP (VoIP) sessions between terminal endpoints such as IP phones and multimedia devices. In H.323 VoIP networks, gatekeeper devices manage call registration, admission, and call status for VoIP calls. The FortiOS h323 session helper supports gatekeepers installed on two different networks or on the same network.

To accept H.323 sessions you must add a security policy with service set to any or to the H323 pre-defined service (which listens on TCP port numbers 1720 and 1503 and on UDP port number 1719). The h323 session helper listens on TCP port 1720.

The ras session helper is used with the h323 session helper for H.323 Registration, Admission, and Status (RAS) services. The ras session helper listens on UDP port 1719.

### **Alternate H.323 gatekeepers**

The h323 session helper supports using H.323 alternate gatekeepers. All the H.323 end points must register with a gatekeeper through the Registration, Admission, and Status (RAS) protocol before they make calls. During the registration process, the primary gatekeeper sends Gatekeeper Confirm (GCF) and Registration Confirm (RCF) messages to the H.323 end points that contain the list of available alternate gatekeepers.

The alternate gatekeeper provides redundancy and scalability for the H.323 end points. If the primary gatekeeper fails the H.323 end points that have registered with that gatekeeper are automatically registered with the alternate gatekeeper. To use the H.323 alternate gatekeeper, you need to configure security policies that allow H.323 end points to reach the alternate gatekeeper.

## **Media Gateway Controller Protocol (MGCP) session helper (mgcp)**

The Media Gateway Control Protocol (MGCP) is a text-based application layer protocol used for VoIP call setup and control. MGCP uses a master-slave call control architecture in which the media gateway controller uses a call agent to maintain call control intelligence, while the media gateways perform the instructions of the call agent.

To accept MGCP sessions you must add a security policy with service set to any or to the MGCP pre-defined service (which listens on UDP port numbers 2427 and 2727). The h323 session helper also listens on UDP port numbers 2427 and 2727.

The MGCP session helper does the following:

- VoIP signalling payload inspection. The payload of the incoming VoIP signalling packet is inspected and malformed packets are blocked.
- Signaling packet body inspection. The payload of the incoming MGCP signaling packet is inspected according to RFC 3435. Malformed packets are blocked.
- Stateful processing of MGCP sessions. State machines are invoked to process the parsed information. Any out-of-state or out-of-transaction packet is identified and properly handled.
- MGCP Network Address Translation (NAT). Embedded IP addresses and ports in packet bodies is properly translated based on current routing information and network topology, and is replaced with the translated IP address and port number, if necessary.
- Manages pinholes for VoIP traffic. To keep the VoIP network secure, the IP address and port information used for media or signalling is identified by the session helper, and pinholes are dynamically created and closed during call setup.

## ONC-RPC portmapper session helper (pmap)

Open Network Computing Remote Procedure Call (ONC-RPC) is a widely deployed remote procedure call system. Also called Sun RPC, ONC-RPC allows a program running on one host to call a program running on another. The transport address of an ONC-RPC service is dynamically negotiated based on the service's program number and version number. Several binding protocols are defined for mapping the RPC program number and version number to a transport address.

To accept ONC-RPC sessions you must add a security policy with service set to any or to the ONC-RPC pre-defined service (which listens on TCP and UDP port number 111). The RPC portmapper session helper (called pmap) handles the dynamic transport address negotiation mechanisms of ONC-RPC.

## PPTP session helper for PPTP traffic (pptp)

The PPTP session help supports port address translation (PAT) for PPTP traffic. PPTP provides IP security at the Network Layer. PPTP consists of a control session and a data tunnel. The control session runs over TCP and helps in establishing and disconnecting the data tunnel. The data tunnel handles encapsulated Point-to-Point Protocol (PPP) packets carried over IP.

To accept PPTP sessions that pass through the FortiGate unit you must add a security policy with service set to any or to the PPTP pre-defined service (which listens on IP port 47 and TCP port 1723). The pptp session helper listens on TCP port 1723.

PPTP uses TCP port 1723 for control sessions and Generic Routing Encapsulation (GRE) (IP protocol 47) for tunneling the encapsulated PPP data. The GRE traffic carries no port number, making it difficult to distinguish between two clients with the same public IP address. PPTP uses the source IP address and the Call ID field in the GRE header to identify a tunnel. When multiple clients sharing the same IP address establish tunnels with the same PPTP server, they may get the same Call ID. The call ID value can be translated in both the control message and the data traffic, but only when the client is in a private network and the server is in a public network.

PPTP clients can either directly connect to the Internet or dial into a network access server to reach the Internet. A FortiGate unit that protects PPTP clients can translate the clients' private IP addresses to a pool of public IP addresses using NAT port translation (NAT-PT). Because the GRE traffic carries no port number for address translation, the pptp session helper treats the Call ID field as a port number as a way of distinguishing multiple clients.

After the PPTP establishing a TCP connection with the PPTP server, the client sends a start control connection request message to establish a control connection. The server replies with a start control connection reply message. The client then sends a request to establish a call and sends an outgoing call request message. FortiOS assigns a Call ID (bytes 12-13 of the control message) that is unique to each PPTP tunnel. The server replies with an outgoing call reply message that carries its own Call ID in bytes 12-13 and the client's call ID in bytes 14-15. The pptp session helper parses the control connection messages for the Call ID to identify the call to which a specific PPP packet belongs. The session helper also identifies an outgoing call request message using the control message type field (bytes 8-9) with the value 7. When the session helper receives this message, it parses the control message for the call ID field (bytes 12-13). FortiOS translates the call ID so that it is unique across multiple calls from the same translated client IP. After receiving outgoing call response message, the session helper holds this message and opens a port that accepts GRE traffic that the PPTP server sends. An outgoing call request message contains the following parts:

- The protocol used for the outgoing call request message (usually GRE)
- Source IP address (PPTP server IP)
- Destination IP address (translated client IP)
- Destination port number (translated client call ID)

The session helper identifies an outgoing call reply message using the control message type field (bytes 8-9) with the value 8. The session helper parses these control messages for the call ID field (bytes 12-13) and the client's call ID (bytes 14-15). The session helper then uses the client's call ID value to find the mapping created for the other direction, and then opens a pinhole to accept the GRE traffic that the client sends.

An outgoing call reply message contains the following parts:

- Protocol used for the outgoing call reply message (usually GRE)
- Source IP address (PPTP client IP)
- Destination IP address (PPTP server IP)
- Destination port number (PPTP server Call ID)

Each port that the session opens creates a session for data traffic arriving in that direction. The session helper opens the following two data sessions for each tunnel:

- Traffic from the PPTP client to the server, using the server's call ID as the destination port
- Traffic from the PPTP server to the client, using the client's translated call ID as the destination port

The default timeout value of the control connection is 30 minutes. The session helper closes the pinhole when the data session exceeds the timeout value or is idle for an extended period.

## Remote shell session helper (rsh)

Using the remote shell program (RSH), authenticated users can run shell commands on remote hosts. RSH sessions most often use TCP port 514. To accept RSH sessions you must add a security policy with service set to any or to the RSH pre-defined service (which listens on TCP port number 514).

FortiOS automatically invokes the rsh session helper to process all RSH sessions on TCP port 514. The rsh session helper opens ports required for the RSH service to operate through a FortiGate unit running NAT or transparent and supports port translation of RSH traffic.

## Real-Time Streaming Protocol (RTSP) session helper (rtsp)

The Real-Time Streaming Protocol (RTSP) is an application layer protocol often used by SIP to control the delivery of multiple synchronized multimedia streams, for example, related audio and video streams. Although RTSP is capable of delivering the data streams itself it is usually used like a network remote control for multimedia servers. The protocol is intended for selecting delivery channels (like UDP, multicast UDP, and TCP) and for selecting a delivery mechanism based on the Real-Time Protocol (RTP). RTSP may also use the SIP Session Description Protocol (SDP) as a means of providing information to clients for aggregate control of a presentation consisting of streams from one or more servers, and non-aggregate control of a presentation consisting of multiple streams from a single server.

To accept RTSP sessions you must add a security policy with service set to any or to the RTSP pre-defined service (which listens on TCP ports 554, 770, and 8554 and on UDP port 554). The rtsp session helper listens on TCP ports 554, 770, and 8554.

The rtsp session help is required because RTSP uses dynamically assigned port numbers that are communicated in the packet body when end points establish a control connection. The session helper keeps track of the port numbers and opens pinholes as required. In Network Address Translation (NAT) mode, the session helper translates IP addresses and port numbers as necessary.

In a typical RTSP session the client starts the session (for example, when the user selects the Play button on a media player application) and establishes a TCP connection to the RTSP server on port 554. The client then sends an OPTIONS message to find out what audio and video features the server supports. The server responds to the OPTIONS message by specifying the name and version of the server, and a session identifier, for example, 24256-1.

The client then sends the DESCRIBE message with the URL of the actual media file the client wants to play. The server responds to the DESCRIBE message with a description of the media in the form of SDP code. The client then sends the SETUP message, which specifies the transport mechanisms acceptable to the client for streamed media, for example RTP/RTCP or RDT, and the ports on which it receives the media.

In a NAT configuration the rtsp session helper keeps track of these ports and addresses translates them as necessary. The server responds to the SETUP message and selects one of the transport protocols. When both client and server agree on a mechanism for media transport the client sends the PLAY message, and the server begins streaming the media.

## Session Initiation Protocol (SIP) session helper (sip)

The sip session helper is described in [“The SIP session helper” on page 2505](#).

## Trivial File Transfer Protocol (TFTP) session helper (tftp)

To accept TFTP sessions you must add a security policy with service set to any or to the TFTP pre-defined service (which listens on UDP port number 69). The TFTP session helper also listens on UTP port number 69.

TFTP initiates transfers on UDP port 69, but the actual data transfer ports are selected by the server and client during initialization of the connection. The tftp session helper reads the transfer ports selected by the TFTP client and server during negotiation and opens these ports on the firewall so that the TFTP data transfer can be completed. When the transfer is complete the tftp session helper closes the open ports.

## Oracle TNS listener session helper (tns)

The Oracle Transparent Network Substrate (TNS) listener listens on port TCP port 1521 for network requests to be passed to a database instance. The Oracle TNS listener session helper (tns) listens for TNS sessions on TCP port 1521. TNS is a foundation technology built into the Oracle Net foundation layer and used by SQLNET.

# Chapter 11 IPsec VPN for FortiOS 5.0

This FortiOS Handbook chapter contains the following sections:

[IPsec VPN concepts](#) explains the basic concepts that you need to understand about virtual private networks (VPNs).

[IPsec VPN Overview](#) provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

[IPsec VPN in the web-based manager](#) describes the IPsec VPN menu of the web-based manager interface.

[Gateway-to-gateway configurations](#) explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN. In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks.

[Hub-and-spoke configurations](#) describes how to set up hub-and-spoke IPsec VPNs. In a hub-and-spoke configuration, connections to a number of remote peers and/or clients radiate from a single, central FortiGate hub.

[Dynamic DNS configuration](#) describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a dynamic IP address and a domain name.

[FortiClient dialup-client configurations](#) guides you through configuring a FortiClient dialup-client IPsec VPN. In a FortiClient dialup-client configuration, the FortiGate unit acts as a dialup server and VPN client functionality is provided by the FortiClient Endpoint Security application installed on a remote host.

[FortiGate dialup-client configurations](#) explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit with a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

[Supporting IKE Mode config clients](#) explains how to set up a FortiGate unit as either an IKE Mode Config server or client. IKE Mode Config is an alternative to DHCP over IPsec.

[Internet-browsing configuration](#) explains how to support secure web browsing performed by dialup VPN clients, and hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

[Redundant VPN configurations](#) discusses the options for supporting redundant and partially redundant tunnels in an IPsec VPN configuration. A FortiGate unit can be configured to support redundant tunnels to the same remote peer if the FortiGate unit has more than one interface to the Internet.

[Transparent mode VPNs](#) describes two FortiGate units that create a VPN tunnel between two separate private networks transparently. In transparent mode, all FortiGate unit interfaces except the management interface are invisible at the network layer.

[IPv6 IPsec VPNs](#) describes FortiGate unit VPN capabilities for networks based on IPv6 addressing. This includes IPv4-over-IPv6 and IPv6-over-IPv4 tunnelling configurations. IPv6 IPsec VPNs are available in FortiOS 3.0 MR5 and later.

[L2TP and IPsec \(Microsoft VPN\)](#) explains how to support Microsoft Windows native VPN clients.

[GRE over IPsec \(Cisco VPN\)](#) explains how to interoperate with Cisco VPNs that use Generic Routing Encapsulation (GRE) protocol with IPsec.

[Protecting OSPF with IPsec](#) provides an example of protecting OSPF links with IPsec.

[Auto Key phase 1 parameters](#) provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The basic phase 1 parameters identify the remote peer or clients and support authentication through preshared keys or digital certificates. You can increase VPN connection security further using methods such as extended authentication (XAuth).

[Phase 2 parameters](#) provides detailed step-by-step procedures for configuring an IPsec VPN tunnel. During phase 2, the specific IPsec security associations needed to implement security services are selected and a tunnel is established.

[Defining VPN security policies](#) explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN tunnel, and how to define a security encryption policy. Security policies control all IP traffic passing between a source address and a destination address.

[Hardware offloading and acceleration](#) explains how to make use of FortiASIC network processor IPsec accelerated processing capabilities.

[Monitoring and troubleshooting](#) provides VPN monitoring and testing procedures

# IPsec VPN concepts

Virtual Private Network (VPN) technology enables remote users to connect to private computer networks to gain access to their resources in a secure way. For example, an employee traveling or working from home can use a VPN to securely access the office network through the Internet.

Instead of remotely logging on to a private network using an unencrypted and unsecure Internet connection, the use of a VPN ensures that unauthorized parties cannot access the office network and cannot intercept any of the information that is exchanged between the employee and the office. It is also common to use a VPN to connect the private networks of two or more offices.

Fortinet offers VPN capabilities in the FortiGate Unified Threat Management (UTM) appliance and in the FortiClient Endpoint Security suite of applications. A FortiGate unit can be installed on a private network, and FortiClient software can be installed on the user's computer. It is also possible to use a FortiGate unit to connect to the private network instead of using FortiClient software.

This chapter discusses VPN terms and concepts including:

- [VPN tunnels](#)
- [VPN gateways](#)
- [Clients, servers, and peers](#)
- [Encryption](#)
- [Authentication](#)
- [Phase 1 and Phase 2 settings](#)
- [Security Association](#)

## VPN tunnels

The data path between a user's computer and a private network through a VPN is referred to as a tunnel. Like a physical tunnel, the data path is accessible only at both ends. In the telecommuting scenario, the tunnel runs between the FortiClient application on the user's PC, or a FortiGate unit or other network device and the FortiGate unit on the office private network.

Encapsulation makes this possible. IPsec packets pass from one end of the tunnel to the other and contain data packets that are exchanged between the local user and the remote private network. Encryption of the data packets ensures that any third-party who intercepts the IPsec packets can not access the data.

**Figure 250:** Encoded data going through a VPN tunnel

You can create a VPN tunnel between:

- a PC equipped with the FortiClient application and a FortiGate unit
- two FortiGate units
- third-party VPN software and a FortiGate unit

Third-party VPN software is not covered in this document. Refer to the [Fortinet Knowledge Base](#) for more information on this topic.

## VPN gateways

A gateway is a router that connects the local network to other networks. The default gateway setting in your computer's TCP/IP properties specifies the gateway for your local network.

A VPN gateway functions as one end of a VPN tunnel. It receives incoming IPsec packets, decrypts the encapsulated data packets and passes the data packets to the local network. Also, it encrypts data packets destined for the other end of the VPN tunnel, encapsulates them, and sends the IPsec packets to the other VPN gateway. The VPN gateway is a FortiGate unit because the private network behind it is protected, ensuring the security of the unencrypted VPN data. The gateway can also be FortiClient software running on a PC since the unencrypted data is secure on the PC.

The IP address of a VPN gateway is usually the IP address of the network interface that connects to the Internet. Optionally, you can define a secondary IP address for the interface and use that address as the local VPN gateway address. The benefit of doing this is that your existing setup is not affected by the VPN settings.

The following diagram shows a VPN connection between two private networks with FortiGate units acting as the VPN gateways. This configuration is commonly referred to as Gateway-to-Gateway IPsec VPN.

**Figure 251:**VPN tunnel between two private networks

Although the IPsec traffic may actually pass through many Internet routers, you can visualize the VPN tunnel as a simple secure connection between the two FortiGate units.

Users on the two private networks do not need to be aware of the VPN tunnel. The applications on their computers generate packets with the appropriate source and destination addresses, as they normally do. The FortiGate units manage all the details of encrypting, encapsulating and sending the packets to the remote VPN gateway.

The data is encapsulated in IPsec packets only in the VPN tunnel between the two VPN gateways. Between the user's computer and the gateway, the data is on the secure private network and it is in regular IP packets.

For example User1 on the Site A network, at IP address 10.10.1.7, sends packets with destination IP address 192.168.10.8, the address of User2 on the Site B network. The Site A FortiGate unit is configured to send packets with destinations on the 192.168.10.0 network through the VPN, encrypted and encapsulated. Similarly, the Site B FortiGate unit is configured to send packets with destinations on the 10.10.1.0 network through the VPN tunnel to the Site A VPN gateway.

In the site-to-site, or gateway-to-gateway VPN shown in [Figure 251](#), the FortiGate units have static (fixed) IP addresses and either unit can initiate communication.

You can also create a VPN tunnel between an individual PC running FortiClient and a FortiGate unit, as shown below. This is commonly referred to as Client-to-Gateway IPsec VPN.

**Figure 252:**VPN tunnel between a FortiClient PC and a FortiGate unit

On the PC, the FortiClient application acts as the local VPN gateway. Packets destined for the office network are encrypted, encapsulated into IPsec packets, and sent through the VPN tunnel to the FortiGate unit. Packets for other destinations are routed to the Internet as usual. IPsec packets arriving through the tunnel are decrypted to recover the original IP packets.

## Clients, servers, and peers

A FortiGate unit in a VPN can have one of the following roles:

- **server** — responds to a request to establish a VPN tunnel.
- **client** — contacts a remote VPN gateway and requests a VPN tunnel.
- **peer** — brings up a VPN tunnel or responds to a request to do so.

The site-to-site VPN shown in [Figure 251](#) is a peer-to-peer relationship. Either FortiGate unit VPN gateway can establish the tunnel and initiate communications. The FortiClient-to-FortiGate VPN shown in [Figure 252](#) is a client-server relationship. The FortiGate unit establishes a tunnel when the FortiClient PC requests one.

A FortiGate unit cannot be a VPN server if it has a dynamically-assigned IP address. VPN clients need to be configured with a static IP address for the server. A FortiGate unit acts as a server only when the remote VPN gateway has a dynamic IP address or is a client-only device or application, such as FortiClient.

As a VPN server, a FortiGate unit can also offer automatic configuration for FortiClient PCs. The user needs to know only the IP address of the FortiGate VPN server and a valid user name/password. FortiClient downloads the VPN configuration settings from the FortiGate VPN server. For information about configuring a FortiGate unit as a VPN server, see the [FortiClient Administration Guide](#).

## Encryption

Encryption mathematically transforms data to appear as meaningless random numbers. The original data is called plaintext and the encrypted data is called ciphertext. The opposite process, called decryption, performs the inverse operation to recover the original plaintext from the ciphertext.

The process by which the plaintext is transformed to ciphertext and back again is called an algorithm. All algorithms use a small piece of information, a key, in the arithmetic process of converted plaintext to ciphertext, or vice-versa. IPsec uses symmetrical algorithms, in which the same key is used to both encrypt and decrypt the data.

The security of an encryption algorithm is determined by the length of the key that it uses. FortiGate IPsec VPNs offer the following encryption algorithms, in descending order of security:

<b>AES256</b>	A 128-bit block algorithm that uses a 256-bit key.
<b>AES192</b>	A 128-bit block algorithm that uses a 192-bit key.
<b>AES128</b>	A 128-bit block algorithm that uses a 128-bit key.
<b>3DES</b>	Triple-DES, in which plain text is DES-encrypted three times by three keys.
<b>DES</b>	Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key

The default encryption algorithms provided on FortiGate units make recovery of encrypted data almost impossible without the proper encryption keys

There is a human factor in the security of encryption. The key must be kept secret, known only to the sender and receiver of the messages. Also, the key must not be something that unauthorized parties might easily guess, such as the sender's name, birthday or simple sequence such as 123456.

## Authentication

In addition to protecting data through encryption, a VPN must ensure that only authorized users can access the private network. You must use either a preshared key on both VPN gateways or RSA X.509 security certificates. The examples in this guide use only preshared key authentication. Refer to the [Fortinet Knowledge Base](#) for articles on RSA X.509 security certificates.

### Preshared keys

A preshared key contains at least six random alphanumeric characters. Users of the VPN must obtain the preshared key from the person who manages the VPN server and add the preshared key to their VPN client configuration.

Although it looks like a password, the preshared key, also known as a shared secret, is never sent by either gateway. The preshared key is used in the calculations at each end that generate

the encryption keys. As soon as the VPN peers attempt to exchange encrypted data, preshared keys that do not match will cause the process to fail.

## Additional authentication

To increase security, you can require additional means of authentication from users:

- an identifier, called a peer ID or a local ID
- extended authentication (XAUTH) which imposes an additional user name/password requirement

A Local ID is an alphanumeric value assigned in the Phase 1 configuration. The Local ID of a peer is called a Peer ID.

## Phase 1 and Phase 2 settings

A VPN tunnel is established in two phases: Phase 1 and Phase 2. Several parameters determine how this is done. Except for IP addresses, the settings simply need to match at both VPN gateways. There are defaults that are appropriate for most cases.

FortiClient distinguishes between Phase 1 and Phase 2 only in the VPN Advanced settings and uses different terms. Phase 1 is called the IKE Policy. Phase 2 is called the IPsec Policy.

### Phase 1

In Phase 1, the two VPN gateways exchange information about the encryption algorithms that they support and then establish a temporary secure connection to exchange authentication information.

When you configure your FortiGate unit or FortiClient application, you must specify the following settings for Phase 1:

<b>Remote Gateway</b>	The remote VPN gateway's address.  FortiGate units also have the option of operating only as a server by selecting the "Dialup User" option.
<b>Preshared key</b>	This must be the same at both ends. It is used to encrypt phase 1 authentication information.
<b>Local interface</b>	The network interface that connects to the other VPN gateway. This applies on a FortiGate unit only.

All other Phase 1 settings have default values. These settings mainly configure the types of encryption to be used. The default settings on FortiGate units and in the FortiClient application are compatible. The examples in this guide use these defaults.

For more detailed information about Phase 1 settings, see the ["Auto Key phase 1 parameters" on page 1637](#).

### Phase 2

Similar to the Phase 1 process, the two VPN gateways exchange information about the encryption algorithms that they support for Phase 2. You may choose different encryption for Phase 1 and Phase 2. If both gateways have at least one encryption algorithm in common, a VPN tunnel can be established. Keep in mind that more algorithms each phase does not share

with the other gateway, the longer negotiations will take. In extreme cases this may cause timeouts during negotiations.

To configure default Phase 2 settings on a FortiGate unit, you need only select the name of the corresponding Phase 1 configuration. In FortiClient, no action is required to enable default Phase 2 settings.

For more detailed information about Phase 2 settings, see [“Phase 2 parameters” on page 1653](#).

## Security Association

The establishment of a Security Association (SA) is the successful outcome of Phase 1 negotiations. Each peer maintains a database of information about VPN connections. The information in each SA can include cryptographic algorithms and keys, keylife, and the current packet sequence number. This information is kept synchronized as the VPN operates. Each SA has a Security Parameter Index (SPI) that is provided to the remote peer at the time the SA is established. Subsequent IPsec packets from the peer always reference the relevant SPI. It is possible for peers to have multiple VPNs active simultaneously, and correspondingly multiple SPIs.

# IPsec VPN Overview

This section provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

The following topics are included in this section:

- [Types of VPNs](#)
- [Planning your VPN](#)
- [General preparation steps](#)
- [How to use this guide to configure an IPsec VPN](#)

VPN configurations interact with the firewall component of the FortiGate unit. There must be a security policy in place to permit traffic to pass between the private network and the VPN tunnel.

Security policies for VPNs specify:

- the FortiGate interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- the FortiGate interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- optionally, a schedule that restricts when the VPN can operate
- optionally, the services (types of data) that can be sent

When the first packet of data that meets all of the conditions of the security policy arrives at the FortiGate unit, a VPN tunnel may be initiated and the encryption or decryption of data is performed automatically afterward. For more information, see [“Defining VPN security policies” on page 1659](#).

## Types of VPNs

FortiGate unit VPNs can be policy-based or route-based. There is little difference between the two types. In both cases, you specify phase 1 and phase 2 settings. However there is a difference in implementation. A route-based VPN creates a virtual IPsec network interface that applies encryption or decryption as needed to any traffic that it carries. That is why route-based VPNs are also known as interface-based VPNs. A policy-based VPN is implemented through a special security policy that applies the encryption you specified in the phase 1 and phase 2 settings.

### Route-based VPNs

For a route-based VPN, you create two security policies between the virtual IPsec interface and the interface that connects to the private network. In one policy the virtual interface is the source. In the other policy the virtual interface is the destination. The Action for both policies is Accept. This creates bidirectional policies that ensure traffic will flow in both directions over the VPN.

## Policy-based VPNs

For a policy-based VPN, one security policy enables communication in both directions. You must select IPSEC as the Action and then select the VPN tunnel you defined in the phase 1 settings. You can then enable inbound and outbound traffic as needed within that policy, or create multiple policies of this type to handle different types of traffic differently. For example HTTPS traffic may not require the same level of scanning as FTP traffic.

## Comparing policy-based or route-based VPNs

For both VPN types you create phase 1 and phase 2 configurations. Both types are handled in the stateful inspection security layer, assuming there is no IPS or AV. For more information on the security layers, see [“Life of a Packet” on page 2271](#).

The main difference is in the security policy.

You create a policy-based VPN by defining an IPSEC security policy between two network interfaces and associating it with the VPN tunnel (phase 1) configuration.

You create a route-based VPN by enabling IPsec interface mode in the VPN phase 1 configuration. This creates a virtual IPsec interface. You then define a regular ACCEPT security policy to permit traffic to flow between the virtual IPsec interface and another network interface. And lastly, configure a static route to allow traffic over the VPN.

Where possible, you should create route-based VPNs. Generally, route-based VPNs are more flexible and easier to configure than policy-based VPNs — by default they are treated as interfaces. However, these two VPN types have different requirements that limit where they can be used.

**Table 71:** Comparison of policy-based and route-based VPNs

Features	Policy-based	Route-based
<ul style="list-style-type: none"><li>Both NAT and transparent modes available</li></ul>	<ul style="list-style-type: none"><li>Yes</li></ul>	<ul style="list-style-type: none"><li>NAT mode only</li></ul>
<ul style="list-style-type: none"><li>L2TP-over-IPsec supported</li></ul>	<ul style="list-style-type: none"><li>Yes</li></ul>	<ul style="list-style-type: none"><li>No</li></ul>
<ul style="list-style-type: none"><li>GRE-over-IPsec supported</li></ul>	<ul style="list-style-type: none"><li>No</li></ul>	<ul style="list-style-type: none"><li>Yes</li></ul>
<ul style="list-style-type: none"><li>security policy requirements</li></ul>	<ul style="list-style-type: none"><li>Requires a security policy with IPSEC action that specifies the VPN tunnel</li></ul>	<ul style="list-style-type: none"><li>Requires only a simple security policy with ACCEPT action</li></ul>
<ul style="list-style-type: none"><li>Number of policies per VPN</li></ul>	<ul style="list-style-type: none"><li>One policy controls connections in both directions</li></ul>	<ul style="list-style-type: none"><li>A separate policy is required for connections in each direction</li></ul>

## Planning your VPN

It is a good idea to plan the VPN configuration ahead of time. This will save time later and help you configure your VPN correctly.

All VPN configurations comprise a number of required and optional parameters. Before you begin, you need to determine:

- where does the IP traffic originate and where does it need to be delivered
- which hosts, servers, or networks to include in the VPN
- which VPN devices to include in the configuration
- through which interfaces the VPN devices communicate
- through which interfaces do private networks access the VPN gateways

Once you have this information, you can select a VPN topology that meets the requirements of your situation.

## Network topologies

The topology of your network will determine how remote peers and clients connect to the VPN and how VPN traffic is routed. You can read about various network topologies and find the high-level procedures needed to configure IPsec VPNs in one of these sections.

**Table 72:** VPN network topologies and brief descriptions

Topology	Description
<a href="#">Gateway-to-gateway configurations</a>	Standard one-to-one VPN between two FortiGate units. See <a href="#">“Gateway-to-gateway configurations” on page 1665</a> .
<a href="#">Hub-and-spoke configurations</a>	One central FortiGate unit has multiple VPNs to other remote FortiGate units. See <a href="#">“Hub-and-spoke configurations” on page 1679</a> .
<a href="#">Dynamic DNS configuration</a>	One end of the VPN tunnel has a changing IP address and the other end must go to a dynamic DNS server for the current IP address before establishing a tunnel. See <a href="#">“Dynamic DNS configuration” on page 1695</a> .
<a href="#">FortiClient dialup-client configurations</a>	Typically remote FortiClient dialup-clients use dynamic IP addresses through NAT devices. The FortiGate unit acts as a dialup server allowing dialup VPN connections from multiple sources. See <a href="#">“FortiClient dialup-client configurations” on page 1709</a> .
<a href="#">FortiGate dialup-client configurations</a>	Similar to FortiClient dialup-client configurations but with more gateway-to-gateway settings such as unique user authentication for multiple users on a single VPN tunnel. See <a href="#">“FortiGate dialup-client configurations” on page 1724</a> .
<a href="#">Internet-browsing configuration</a>	Secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. See <a href="#">“Internet-browsing configuration” on page 1737</a> .
<a href="#">Redundant VPN configurations</a>	Options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches. See <a href="#">“Redundant VPN configurations” on page 1741</a> .
<a href="#">Transparent mode VPNs</a>	In transparent mode, the FortiGate acts as a bridge with all incoming traffic being broadcast back out on all other interfaces. Routing and NAT must be performed on external routers. See <a href="#">“Transparent mode VPNs” on page 1766</a> .

**Table 72:** VPN network topologies and brief descriptions

Topology	Description
<a href="#">Manual-key configurations</a>	Manually define cryptographic keys to establish an IPsec VPN, either policy-based or route-based. See <a href="#">“Manual-key configurations” on page 1770</a> .
<a href="#">L2TP and IPsec (Microsoft VPN)</a>	Configure VPN for Microsoft Windows dialup clients using the built in L2TP software. Users do not have to install any See <a href="#">“L2TP and IPsec (Microsoft VPN)” on page 1786</a> .

These sections contain high-level configuration guidelines with cross-references to detailed configuration procedures. If you need more detail to complete a step, select the cross-reference in the step to drill-down to more detail. Return to the original procedure to complete the procedure. For a general overview of how to configure a VPN, see [“General preparation steps”](#) below.

## General preparation steps

A VPN configuration defines relationships between the VPN devices and the private hosts, servers, or networks making up the VPN. Configuring a VPN involves gathering and recording the following information. You will need this information to configure the VPN.

- **The private IP addresses of participating hosts, servers, and/or networks.** These IP addresses represent the source addresses of traffic that is permitted to pass through the VPN. A IP source address can be an individual IP address, an address range, or a subnet address.
- **The public IP addresses of the VPN end-point interfaces.** The VPN devices establish tunnels with each other through these interfaces.
- **The private IP addresses associated with the VPN-device interfaces to the private networks.** Computers on the private networks behind the VPN gateways will connect to their VPN gateways through these interfaces.

## How to use this guide to configure an IPsec VPN

This guide uses a task-based approach to provide all of the procedures needed to create different types of VPN configurations. Follow the step-by-step configuration procedures in this guide to set up the VPN.

The following configuration procedures are common to all IPsec VPNs:

1. Define the phase 1 parameters that the FortiGate unit needs to authenticate remote peers or clients and establish a secure a connection. See [“Auto Key phase 1 parameters” on page 1637](#).
2. Define the phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with a remote peer or dialup client. See [“Phase 2 parameters” on page 1653](#).
3. Specify the source and destination addresses of IP packets that are to be transported through the VPN tunnel. See [“Defining policy addresses” on page 1659](#).
4. Create an IPsec security policy to define the scope of permitted services between the IP source and destination addresses. See [“Defining VPN security policies” on page 1660](#).

# IPsec VPN in the web-based manager

The IPsec VPN menu in FortiOS provides settings to configure an IPsec VPN. IPsec VPNs that are configured by using the general procedure below. With these steps, your FortiGate unit will automatically generate unique IPsec encryption and authentication keys.

1. Define phase 1 parameters to authenticate remote peers and clients for a secure connection. See [“Phase 1 configuration” on page 1625](#).
2. Define phase 2 parameters to create a VPN tunnel with a remote peer or dialup client. See [“Phase 2 configuration” on page 1629](#).
3. Create a security policy to permit communication between your private network and the VPN. Policy-based VPNs have an action of IPSEC, where for interface-based VPNs the security policy action is ACCEPT. See [“Defining VPN security policies” on page 1659](#).

The FortiGate unit implements the Encapsulated Security Payload (ESP) protocol. Internet Key Exchange (IKE) is performed automatically based on pre-shared keys or X.509 digital certificates. Interface mode, supported in NAT mode only, creates a virtual interface for the local end of a VPN tunnel.

This topic contains the following:

- [Auto Key \(IKE\)](#)
- [Manual Key](#)
- [Concentrator](#)

## Auto Key (IKE)

You can configure VPN peers (or a FortiGate dialup server and a VPN client) to generate unique Internet Key Exchange (IKE) keys automatically during the IPsec phase 1 and phase 2 exchanges.

When you define phase 2 parameters, you can choose any set of phase 1 parameters to set up a secure connection for the tunnel and authenticate the remote peer. Auto Key configuration applies to both tunnel-mode and interface-mode VPNs.

To configure VPN peers go to *VPN > IPsec > Auto Key (IKE)*.

<b>Create Phase 1</b>	Creates a new phase 1 tunnel configuration. For more information, see <a href="#">“Phase 1 configuration” on page 1625</a> .
<b>Create Phase 2</b>	Creates a new phase 2 configuration. For more information, see <a href="#">“Phase 2 configuration” on page 1629</a> .
<b>Create FortiClient VPN</b>	Creates a new FortiClient VPN. For more information, see <a href="#">“FortiClient VPN” on page 1632</a> .

If you want to control how the IKE negotiation process controls traffic when there is no traffic, as well as the length of time the FortiGate unit waits for negotiations to occur, use the `negotiation-timeout` and `auto-negotiation` commands in the CLI.

## Phase 1 configuration

The basic phase 1 settings associate IPsec phase 1 parameters with a remote gateway, if a pre-shared key or digital certificate will be used, and if a special identifier will be used to identify the remote VPN peer or client.

<b>Name</b>	<p>Type a name for the phase 1 definition. The maximum name length is 15 characters for an interface mode VPN, 35 characters for a policy-based VPN. If <i>Remote Gateway</i> is <i>Dialup User</i>, the maximum name length is further reduced depending on the number of dialup tunnels that can be established: by 2 for up to 9 tunnels, by 3 for up to 99 tunnels, 4 for up to 999 tunnels, and so on.</p> <p>For a tunnel mode VPN, the name normally reflects where the remote connection originates. For a route-based tunnel, the FortiGate unit also uses the name for the virtual IPsec interface that it creates automatically.</p>
<b>Remote Gateway</b>	<p>Select the category of the remote connection:</p> <ul style="list-style-type: none"><li>• <i>Static IP Address</i> — If the remote peer has a static IP address.</li><li>• <i>Dialup User</i> — If one or more FortiClient or FortiGate dialup clients with dynamic IP addresses will connect to the FortiGate unit.</li><li>• <i>Dynamic DNS</i> — If a remote peer that has a domain name and subscribes to a dynamic DNS service will connect to the FortiGate unit.</li></ul>
<b>IP Address</b>	<p>If you selected <i>Static IP Address</i>, enter the IP address of the remote peer.</p>
<b>Dynamic DNS</b>	<p>If you selected <i>Dynamic DNS</i>, enter the domain name of the remote peer.</p>
<b>Local Interface</b>	<p>This option is available in NAT mode only. Select the name of the interface through which remote peers or dialup clients connect to the FortiGate unit.</p> <p>By default, the local VPN gateway IP address is the IP address of the interface that you selected. Optionally, you can specify a unique IP address for the VPN gateway in the <i>Advanced</i> settings.</p>
<b>Mode</b>	<ul style="list-style-type: none"><li>• <i>Main mode</i> — the phase 1 parameters are exchanged in multiple rounds with encrypted authentication information.</li><li>• <i>Aggressive mode</i> — the phase 1 parameters are exchanged in single message with authentication information that is not encrypted.</li></ul> <p>When the remote VPN peer has a dynamic IP address and is authenticated by a pre-shared key, you must select Aggressive mode if there is more than one dialup phase1 configuration for the interface IP address.</p> <p>When the remote VPN peer has a dynamic IP address and is authenticated by a certificate, you must select Aggressive mode if there is more than one phase 1 configuration for the interface IP address and these phase 1 configurations use different proposals.</p>
<b>Authentication Method</b>	<p>Select <i>Preshared Key</i> or <i>RSA Signature</i>.</p>

<b>Pre-shared Key</b>	If you selected <i>Pre-shared Key</i> , enter the pre-shared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during phase 1 negotiations. You must define the same key at the remote peer or client. The key must contain at least 6 printable characters. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.
<b>Certificate Name</b>	If you selected <i>RSA Signature</i> , select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during phase 1 negotiations. For information about obtaining and loading the required server certificate, see the <a href="#">FortiOS User Authentication guide</a> .
<b>Peer Options</b>	Peer options are available to authenticate VPN peers or clients, depending on the <i>Remote Gateway</i> and <i>Authentication Method</i> settings.
<b>Accept any peer ID</b>	<p>Accept the local ID of any remote VPN peer or client. The FortiGate unit does not check identifiers (local IDs). You can set <i>Mode</i> to <i>Aggressive</i> or <i>Main</i>.</p> <p>You can use this option with RSA Signature authentication. But, for highest security, configure a PKI user/group for the peer and set <i>Peer Options</i> to <i>Accept this peer certificate only</i>.</p>
<b>Accept this peer ID</b>	<p>This option is available when <i>Aggressive Mode</i> is enabled. Enter the identifier that is used to authenticate the remote peer. This identifier must match the Local ID that the remote peer's administrator has configured.</p> <p>If the remote peer is a FortiGate unit, the identifier is specified in the <i>Local ID</i> field of the Advanced phase 1 configuration.</p> <p>If the remote peer is a FortiClient user, the identifier is specified in the <i>Local ID</i> field, accessed by selecting <i>Config</i> in the <i>Policy</i> section of the VPN connection's <i>Advanced Settings</i>.</p>
<b>Accept peer ID in dialup group</b>	<p>Authenticate multiple FortiGate or FortiClient dialup clients that use unique identifiers and unique pre-shared keys (or unique pre-shared keys only) through the same VPN tunnel.</p> <p>You must create a dialup user group for authentication purposes. Select the group from the list next to the <i>Accept peer ID in dialup group</i> option.</p> <p>You must set <i>Mode</i> to <i>Aggressive</i> when the dialup clients use unique identifiers and unique pre-shared keys. If the dialup clients use unique pre-shared keys only, you can set <i>Mode</i> to <i>Main</i> if there is only one dialup phase 1 configuration for this interface IP address.</p>
<b>Advanced</b>	Defines advanced phase 1 parameters. For more information, see <a href="#">Phase 1 advanced configuration settings</a> .

## Phase 1 advanced configuration settings

You use the advanced parameters to select the encryption and authentication algorithms that the FortiGate unit uses to generate keys for the IKE exchange. You can also select these advanced settings to ensure the smooth operation of phase 1 negotiations.

To configure Phase 1 settings, go to *VPN > Auto Key (IKE)* and select *Create Phase 1*.

<b>Enable IPsec Interface Mode</b>	<p>This is available in NAT mode only.</p> <p>Create a virtual interface for the local end of the VPN tunnel. Select this option to create a route-based VPN, clear it to create a policy-based VPN.</p>
<b>IKE Version</b>	<p>Select the version of IKE to use. This is available only if <i>IPsec Interface Mode</i> is enabled. For more information about IKE v2, refer to RFC 4306.</p> <p>IKE v2 is not available if <i>Mode</i> is <i>Aggressive</i>.</p> <p>When <i>IKE Version</i> is 2, <i>Mode</i> and <i>XAUTH</i> are not available.</p>
<b>IPv6 Version</b>	<p>Select if you want to use IPv6 addresses for the remote gateway and interface IP addresses. This is available only when <i>Enable IPsec Interface Mode</i> is selected and IPv6 Support is enabled in the administrative settings (<i>System &gt; Admin &gt; Settings</i>).</p>
<b>Local Gateway IP</b>	<p>If you selected <i>Enable IPsec Interface Mode</i>, specify an IP address for the local end of the VPN tunnel. Select one of the following:</p> <ul style="list-style-type: none"><li>• <i>Main Interface IP</i> — The FortiGate unit obtains the IP address of the interface from the network interface settings.</li><li>• <i>Specify</i> — Enter a secondary address of the interface selected in the phase 1 <i>Local Interface</i> field.</li></ul> <p>You cannot configure Interface mode in a transparent mode VDOM.</p>
<b>P1 Proposal</b>	<p>Select the encryption and authentication algorithms used to generate keys for protecting negotiations and add encryption and authentication algorithms as required.</p> <p>You need to select a minimum of one and a maximum of three combinations. The remote peer or client must be configured to use at least one of the proposals that you define.</p> <p>Select one of the following symmetric-key encryption algorithms:</p> <ul style="list-style-type: none"><li>• <i>DES</i> — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.</li><li>• <i>3DES</i> — Triple-DES, in which plain text is encrypted three times by three keys.</li><li>• <i>AES128</i> — a 128-bit block Cipher Block Chaining (CBC) algorithm that uses a 128-bit key.</li><li>• <i>AES192</i> — a 128-bit block Cipher Block Chaining (CBC) algorithm that uses a 192-bit key.</li><li>• <i>AES256</i> — a 128-bit block Cipher Block Chaining (CBC) algorithm that uses a 256-bit key.</li></ul>

	<p>Select either of the following authentication message digests to check the authenticity of messages during phase 1 negotiations:</p> <ul style="list-style-type: none"> <li>• <i>MD5</i> — Message Digest 5, the hash algorithm developed by RSA Data Security.</li> <li>• <i>SHA1</i> — Secure Hash Algorithm 1, which produces a 160-bit message digest.</li> <li>• <i>SHA256</i> — Secure Hash Algorithm 2, which produces a 256-bit message digest.</li> </ul> <p>To specify a third combination, use the <i>Add</i> button beside the fields for the second combination.</p>
<b>DH Group</b>	<p>Select one or more Diffie-Hellman groups from DH group 1, 2, 5 and 14. At least one of the <i>DH Group</i> settings on the remote peer or client must match one the selections on the FortiGate unit. Failure to match one or more DH groups will result in failed negotiations.</p>
<b>Keylife</b>	<p>Enter the time (in seconds) that must pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172 800 seconds.</p>
<b>Local ID</b>	<p>If the FortiGate unit will act as a VPN client and you are using peer IDs for authentication purposes, enter the identifier that the FortiGate unit will supply to the VPN server during the phase 1 exchange.</p> <p>If the FortiGate unit will act as a VPN client, and you are using security certificates for authentication, select the distinguished name (DN) of the local server certificate that the FortiGate unit will use for authentication purposes.</p> <p>If the FortiGate unit is a dialup client and will not be sharing a tunnel with other dialup clients (that is, the tunnel will be dedicated to this Fortinet dialup client), set <i>Mode</i> to <i>Aggressive</i>.</p> <p>Note that this Local ID value must match the peer ID value given for the remote VPN peer's Peer Options.</p>
<b>XAuth</b>	<p>This option supports the authentication of dialup clients. It is available for IKE v1 only.</p> <ul style="list-style-type: none"> <li>• <i>Disable</i> — Select if you do not use XAuth.</li> <li>• <i>Enable as Client</i> — If the FortiGate unit is a dialup client, enter the user name and password that the FortiGate unit will need to authenticate itself to the remote XAuth server.</li> <li>• <i>Enable as Server</i> — This is available only if <i>Remote Gateway</i> is set to <i>Dialup User</i>. Dialup clients authenticate as members of a dialup user group. You must first create a user group for the dialup clients that need access to the network behind the FortiGate unit.</li> </ul> <p>You must also configure the FortiGate unit to forward authentication requests to an external RADIUS or LDAP authentication server.</p> <p>Select a <i>Server Type</i> setting to determine the type of encryption method to use between the FortiGate unit, the XAuth client and the external authentication server, and then select the user group from the User Group list.</p>
<b>Username</b>	<p>Enter the user name that is used for authentication.</p>

<b>Password</b>	Enter the password that is used for authentication.
<b>NAT Traversal</b>	Select the check box if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared) to connect reliably.
<b>Keepalive Frequency</b>	If you enabled <i>NAT-traversal</i> , enter a keepalive frequency setting.
<b>Dead Peer Detection</b>	<p>Select this check box to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. You can use this option to receive notification whenever a tunnel goes up or down, or to keep the tunnel connection open when no traffic is being generated inside the tunnel. For example, in scenarios where a dialup client or dynamic DNS peer connects from an IP address that changes periodically, traffic may be suspended while the IP address changes.</p> <p>With <i>Dead Peer Detection</i> selected, you can use the <code>config vpn ipsec phase1</code> (tunnel mode) or <code>config vpn ipsec phase1-interface</code> (interface mode) CLI command to optionally specify a retry count and a retry interval.</p>

## Phase 2 configuration

After IPsec phase 1 negotiations end successfully, you begin phase 2. You configure the phase 2 parameters to define the algorithms that the FortiGate unit may use to encrypt and transfer data for the remainder of the session. During phase 2, you select specific IPsec security associations needed to implement security services and establish a tunnel.

The basic phase 2 settings associate IPsec phase 2 parameters with the phase 1 configuration that specifies the remote end point of the VPN tunnel. In most cases, you need to configure only basic phase 2 settings.

To configure Phase 2 settings, go to *VPN > Auto Key (IKE)* and select *Create Phase 2*.

<b>Name</b>	Type a name to identify the phase 2 configuration.
<b>Phase 1</b>	Select the phase 1 tunnel configuration. For more information on configuring phase 1, see <a href="#">“Phase 1 configuration” on page 1625</a> . The phase 1 configuration describes how remote VPN peers or clients will be authenticated on this tunnel, and how the connection to the remote peer or client will be secured.
<b>Advanced</b>	Define advanced phase 2 parameters. For more information, see <a href="#">“Phase 2 advanced configuration settings” on page 1629</a> .

## Phase 2 advanced configuration settings

In phase 2, the FortiGate unit and the VPN peer or client exchange keys again to establish a secure communication channel between them. You select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). These are called P2 Proposal parameters. The keys are generated automatically using a Diffie-Hellman algorithm.

You can use a number of additional advanced phase 2 settings to enhance the operation of the tunnel.

<b>P2 Proposal</b>	<p>Select the encryption and authentication algorithms that will be proposed to the remote VPN peer. You can specify up to three proposals. To establish a VPN connection, at least one of the proposals that you specify must match configuration on the remote peer.</p> <p>Initially there are two proposals. <i>Add</i> and <i>Delete</i> icons are next to the second <i>Authentication</i> field.</p> <p>It is invalid to set both <i>Encryption</i> and <i>Authentication</i> to NULL.</p>
<b>Encryption</b>	<p>Select one of the following symmetric-key algorithms:</p> <ul style="list-style-type: none"><li>• <i>NULL</i> — Do not use an encryption algorithm.</li><li>• <i>DES</i> — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.</li><li>• <i>3DES</i> — Triple-DES, in which plain text is encrypted three times by three keys.</li><li>• <i>AES128</i> — a 128-bit block Cipher Block Chaining (CBC) algorithm that uses a 128-bit key.</li><li>• <i>AES192</i> — a 128-bit block CBC algorithm that uses a 192-bit key.</li><li>• <i>AES256</i> — a 128-bit block CBC algorithm that uses a 256-bit key.</li></ul>
<b>Authentication</b>	<p>Select one of the following message digests to check the authenticity of messages during an encrypted session:</p> <ul style="list-style-type: none"><li>• <i>NULL</i> — Do not use a message digest.</li><li>• <i>MD5</i> — Message Digest 5, the hash algorithm developed by RSA Data Security.</li><li>• <i>SHA1</i> — Secure Hash Algorithm 1, which produces a 160-bit message digest.</li><li>• <i>SHA256</i> — Secure Hash Algorithm 2, which produces a 256-bit message digest.</li><li>• <i>SHA384</i> — Secure Hash Algorithm 2, which produces a 384-bit message digest.</li><li>• <i>SHA512</i> — Secure Hash Algorithm 2, which produces a 512-bit message digest.</li></ul>
<b>Enable replay detection</b>	<p>Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.</p>
<b>Enable perfect forward secrecy (PFS)</b>	<p>Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.</p>
<b>DH Group</b>	<p>Select one Diffie-Hellman group (1, 2, 5 or 14). This must match the DH Group that the remote peer or dialup client uses.</p>
<b>Keylife</b>	<p>Select the method for determining when the phase 2 key expires: <i>Seconds</i>, <i>KBytes</i>, or <i>Both</i>. If you select <i>Both</i>, the key expires when either the time has passed or the number of KB have been processed.</p>
<b>Autokey Keep Alive</b>	<p>Select the check box if you want the tunnel to remain active when no data is being processed.</p>

<b>DHCP-IPSec</b>	<p>Provide IP addresses dynamically to VPN clients. This is available for phase 2 configurations associated with a dialup phase 1 configuration.</p> <p>You also need configure a DHCP server or relay on the private network interface. You must configure the DHCP parameters separately.</p> <p>If you configure the DHCP server to assign IP addresses based on RADIUS user group attributes, you must also set the Phase 1 <i>Peer Options to Accept peer ID in dialup group</i> and select the appropriate user group. See <a href="#">“Phase 1 configuration” on page 1625</a>.</p> <p>If the FortiGate unit acts as a dialup server and you manually assigned FortiClient dialup clients VIP addresses that match the network behind the dialup server, selecting the check box will cause the FortiGate unit to act as a proxy for the dialup clients.</p>
<b>Quick Mode Selector</b>	<p>Specify the source and destination IP addresses to be used as selectors for IKE negotiations. If the FortiGate unit is a dialup server, keep the default value of 0.0.0.0/0 unless you need to circumvent problems caused by ambiguous IP addresses between one or more of the private networks making up the VPN. You can specify a single host IP address, an IP address range, or a network address. You may optionally specify source and destination port numbers and a protocol number.</p> <p>If you are editing an existing phase 2 configuration, the <i>Source address</i> and <i>Destination address</i> fields are unavailable if the tunnel has been configured to use firewall addresses as selectors. This option exists only in the CLI.</p>
<b>Source address</b>	<p>If the FortiGate unit is a dialup server, enter the source IP address that corresponds to the local senders or network behind the local VPN peer (for example, 172.16.5.0/24 or 172.16.5.0/255.255.255.0 for a subnet, or 172.16.5.1/32 or 172.16.5.1/255.255.255.255 for a server or host, or 192.168.10.[80-100] or 192.168.10.80-192.168.10.100 for an address range). A value of 0.0.0.0/0 means all IP addresses behind the local VPN peer.</p> <p>If the FortiGate unit is a dialup client, source address must refer to the private network behind the Fortinet dialup client.</p>
<b>Source port</b>	<p>Enter the port number that the local VPN peer uses to transport traffic related to the specified service (protocol number). The range is from 0 to 65535. To specify all ports, type 0.</p>
<b>Destination address</b>	<p>Enter the destination IP address that corresponds to the recipients or network behind the remote VPN peer (for example, 192.168.20.0/24 for a subnet, or 172.16.5.1/32 for a server or host, or 192.168.10.[80-100] for an address range). A value of 0.0.0.0/0 means all IP addresses behind the remote VPN peer.</p>
<b>Destination port</b>	<p>Enter the port number that the remote VPN peer uses to transport traffic related to the specified service (protocol number). To specify all ports, enter 0.</p>
<b>Protocol</b>	<p>Enter the IP protocol number of the service. To specify all services, enter 0.</p>

## FortiClient VPN

Use the FortiClient VPN configuration settings when configuring an IPsec VPN for remote users to connect to the VPN tunnel using FortiClient.

To create a FortiClient VPN tunnel, go to *VPN > IPsec > Auto Key (IKE)* and select *Create FortiClient VPN* at the top of the screen.

When configuring a FortiClient VPN connection, the settings for phase 1 and phase 2 settings are automatically configured by the FortiGate unit. They are set to:

- Remote Gateway — Dialup User
- Mode — Aggressive
- IPsec Interface Mode — Enabled
- Default settings for P1 and P2 Proposal
- XAUTH Enable as Server (Auto)
- IKE mode-config will be enabled
- Peer Option — “Accept any peer ID”

The remainder of the settings use the current FortiGate defaults. Note that FortiClient settings need to match these FortiGate defaults. If you need to configure advanced settings for the FortiClient VPN, select *Edit* on the Auto Key (IKE) page (Go to *VPN > IPsec > Auto Key (IKE)*) and configure the peer options or advanced options.

<b>Name</b>	Enter a name for the FortiClient VPN.
<b>Local Outgoing Interface</b>	Select the local outgoing interface for the VPN.
<b>Authentication Method</b>	Select the type of authentication used when logging in to the VPN.
<b>Preshared Key</b>	If <i>Pre-shared Key</i> was selected in <i>Authentication Method</i> , enter the pre-shared key in the field provided.
<b>User Group</b>	Select a user group. You can also create a user group from the drop-down list by selecting <i>Create New</i> .
<b>Address Range Start IP</b>	Enter the start IP address for the DHCP address range for the client.
<b>Address Range End IP</b>	Enter the end IP address for the address range.
<b>Subnet Mask</b>	Enter the subnet mask.
<b>Enable IPv4 Split Tunnel</b>	Enabled by default, this option enables the FortiClient user to use the VPN to access internal resources while other Internet access is not sent over the VPN, alleviating potential traffic bottlenecks in the VPN connection. Disable this option to have all traffic sent through the VPN tunnel.
<b>Accessible Networks</b>	Select from a list of internal networks that the FortiClient user can access.

<b>Client Options</b>	<p>These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default.</p> <p><b>Save Password</b> - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN.</p> <p><b>Auto Connect</b> - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel.</p> <p><b>Always Up (Keep Alive)</b> - When enabled, if the user selects this option, the FortiClient connection will not shut down. When not selected, during periods of inactivity, FortiClient will attempt to stay connected every three minutes for a maximum of 10 minutes.</p>
<b>Endpoint Registration</b>	<p>When selected, the FortiGate unit requests a registration key from FortiClient before a connection can be established. A registration key is defined by going to <i>System &gt; Config &gt; Advanced</i>.</p> <p>For more information on FortiClient VPN connections to a FortiGate unit, see the <i>FortiClient Administration Guide</i>.</p>
<b>DNS Server</b>	<p>Select which DNS server to use for this VPN:</p> <ul style="list-style-type: none"> <li>• <i>Use System DNS</i> — Use the same DNS servers as the FortiGate unit. These are configured at <i>System &gt; Interface &gt; DNS</i>. This is the default option.</li> <li>• <i>Specify</i> — Specify the IP address of a different DNS server.</li> </ul>

## Manual Key

Use manual keys only if it is unavoidable. There are potential difficulties in keeping keys confidential and in propagating changed keys to remote VPN peers securely.

If required, you can manually define cryptographic keys for establishing an IPsec VPN tunnel. You would define manual keys in situations where:

- you require prior knowledge of the encryption or authentication key (that is, one of the VPN peers requires a specific IPsec encryption or authentication key).
- you need to disable encryption and authentication.

In both cases, you do not specify IPsec phase 1 and phase 2 parameters; you define manual keys from the CLI using the `config vpn ipsec manualkey` command.

### Manual key configuration settings

If one of the VPN devices is manually keyed, the other VPN device must also be manually keyed with the identical authentication and encryption keys. In addition, it is essential that both VPN devices be configured with complementary Security Parameter Index (SPI) settings. The administrators of the devices need to cooperate to achieve this.

If you are not familiar with the security policies, SAs, selectors, and SA databases for your particular installation, do not attempt these procedures without qualified assistance.

Each SPI identifies a Security Association (SA). The value is placed in ESP datagrams to link the datagrams to the SA. When an ESP datagram is received, the recipient refers to the SPI to determine which SA applies to the datagram. You must manually specify an SPI for each SA. There is an SA for each direction, so for each VPN you must specify two SPIs, a local SPI and a remote SPI, to cover bidirectional communications between two VPN devices.

<b>Name</b>	Type a name for the VPN tunnel. The maximum name length is 15 characters for an interface mode VPN, 35 characters for a policy-based VPN.
<b>Local SPI</b>	Type a hexadecimal number (up to 8 characters, 0-9, a-f) that represents the SA that handles outbound traffic on the local FortiGate unit. The valid range is from 0x100 to 0xffffffff. This value must match the Remote SPI value in the manual key configuration at the remote peer.
<b>Remote SPI</b>	Type a hexadecimal number (up to 8 characters, 0-9, a-f) that represents the SA that handles inbound traffic on the local FortiGate unit. The valid range is from 0x100 to 0xffffffff. This value must match the Local SPI value in the manual key configuration at the remote peer.
<b>Remote Gateway</b>	Enter the IP address of the public interface to the remote peer. The address identifies the recipient of ESP datagrams.
<b>Local Interface</b>	This option is available in NAT mode only. Select the name of the interface to which the IPsec tunnel will be bound. The FortiGate unit obtains the IP address of the interface from the network interface settings.
<b>Encryption Algorithm</b>	<p>Select one of the following symmetric-key encryption algorithms:</p> <ul style="list-style-type: none"> <li>• <i>NULL</i> — Do not use an encryption algorithm.</li> <li>• <i>DES</i> — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.</li> <li>• <i>3DES</i> — Triple-DES, where plain text is encrypted three times by three keys.</li> <li>• <i>AES128</i> — a 128-bit block Cipher Block Chaining algorithm that uses a 128-bit key.</li> <li>• <i>AES192</i> — a 128-bit block Cipher Block Chaining ) algorithm that uses a 192-bit key.</li> <li>• <i>AES256</i> — a 128-bit block Cipher Block Chaining algorithm that uses a 256-bit key.</li> </ul> <p><b>Note:</b> The algorithms for encryption and authentication cannot both be NULL.</p>

<b>Authentication Algorithm</b>	<p>Select one of the following message digests:</p> <ul style="list-style-type: none"> <li>• <i>NULL</i> — Do not use a message digest.</li> <li>• <i>MD5</i> — Message Digest 5 algorithm, which produces a 128-bit message digest.</li> <li>• <i>SHA1</i> — Secure Hash Algorithm 1, which produces a 160-bit message digest.</li> <li>• <i>SHA256</i> — Secure Hash Algorithm 2, which produces a 256-bit message digest.</li> <li>• <i>SHA384</i> — Secure Hash Algorithm 2, which produces a 384-bit message digest.</li> <li>• <i>SHA512</i> — Secure Hash Algorithm 2, which produces a 512-bit message digest.</li> </ul> <p><b>Note:</b> The Algorithms for encryption and authentication cannot both be NULL.</p>
<b>IPsec Interface Mode</b>	<p>Create a virtual interface for the local end of the VPN tunnel. Select this check box to create a route-based VPN, clear it to create a policy-based VPN.</p> <p>This is available only in NAT mode.</p>

## Concentrator

In a hub-and-spoke configuration, policy-based VPN connections to a number of remote peers radiate from a single, central FortiGate unit. Site-to-site connections between the remote peers do not exist; however, you can establish VPN tunnels between any two of the remote peers through the FortiGate unit's "hub".

In a hub-and-spoke network, all VPN tunnels terminate at the hub. The peers that connect to the hub are known as "spokes". The hub functions as a concentrator on the network, managing all VPN connections between the spokes. VPN traffic passes from one tunnel to the other through the hub.

You define a concentrator to include spokes in the hub-and-spoke configuration. You create the concentrator in *VPN > IPsec > Concentrator* and select *Create New*. A concentrator configuration specifies which spokes to include in an IPsec hub-and-spoke configuration.

<b>Concentrator Name</b>	Type a name for the concentrator.
<b>Available Tunnels</b>	A list of defined IPsec VPN tunnels. Select a tunnel from the list and then select the right arrow.
<b>Members</b>	A list of tunnels that are members of the concentrator. To remove a tunnel from the concentrator, select the tunnel and select the left arrow.

## IPsec Monitor

You can use the IPsec Monitor to view activity on IPsec VPN tunnels and start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels, including tunnel mode and route-based (interface mode) tunnels.

To view the IPsec monitor, go to *VPN > Monitor > IPsec Monitor*.

For dialup VPNs, the list provides status information about the VPN tunnels established by dialup clients, and their IP addresses.

For static IP or dynamic DNS VPNs, the list provides status and IP addressing information about VPN tunnels, active or not, to remote peers that have static IP addresses or domain names. You can also start and stop individual tunnels from the list.

# Auto Key phase 1 parameters

This chapter provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The phase 1 parameters identify the remote peer or clients and support authentication through preshared keys or digital certificates. You can increase access security further using peer identifiers, certificate distinguished names, group names, or the FortiGate extended authentication (XAuth) option for authentication purposes.

For more information on phase 1 parameters in the web-based manager, see [“Phase 1 configuration” on page 1625](#).

The following topics are included in this section:

- [Overview](#)
- [Defining the tunnel ends](#)
- [Choosing main mode or aggressive mode](#)
- [Authenticating the FortiGate unit](#)
- [Authenticating remote peers and clients](#)
- [Defining IKE negotiation parameters](#)
- [Using XAuth authentication](#)

## Overview

To configure IPsec phase 1 settings, go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 1*. IPsec phase 1 settings define:

- the remote and local ends of the IPsec tunnel
- if phase 1 parameters are exchanged in multiple rounds with encrypted authentication information (main mode) or in a single message with authentication information that is not encrypted (aggressive mode)
- if a preshared key or digital certificates will be used to authenticate the FortiGate unit to the VPN peer or dialup client
- if the VPN peer or dialup client is required to authenticate to the FortiGate unit. A remote peer or dialup client can authenticate by peer ID or, if the FortiGate unit authenticates by certificate, it can authenticate by peer certificate.
- the IKE negotiation proposals for encryption and authentication
- optional XAuth authentication, which requires the remote user to enter a user name and password. A FortiGate VPN server can act as an XAuth server to authenticate dialup users. A FortiGate unit that is a dialup client can also be configured as an XAuth client to authenticate itself to the VPN server.

For all the phase 1 web-based manager fields, see [“Phase 1 configuration” on page 1625](#).

If you want to control how the IKE negotiation process controls traffic when there is no traffic, as well as the length of time the unit waits for negotiations to occur, use the `negotiation-timeout` and `auto-negotiation` commands in the CLI.

## Defining the tunnel ends

To begin defining the phase 1 configuration, go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 1*. Enter a descriptive name for the VPN tunnel. This is particularly important if you will create several tunnels.

The phase 1 configuration mainly defines the ends of the IPsec tunnel. The remote end is the remote gateway with which the FortiGate unit exchanges IPsec packets. The local end is the FortiGate interface that sends and receives IPsec packets.

The remote gateway can be:

- a static IP address
- a domain name with a dynamic IP address
- a dialup client

A statically addressed remote gateway is the simplest to configure. You specify the IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer has a domain name and subscribes to a dynamic DNS service, you need to specify only the domain name. The FortiGate unit performs a DNS query to determine the appropriate IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer is a dialup client, only the dialup client can bring up the tunnel. The IP address of the client is not known until it connects to the FortiGate unit. This configuration is a typical way to provide a VPN for client PCs running VPN client software such as the FortiClient Endpoint Security application.

The local end of the VPN tunnel, the Local Interface, is the FortiGate interface that sends and receives the IPsec packets. This is usually the public interface of the FortiGate unit that is connected to the Internet (typically the WAN1 port). Packets from this interface pass to the private network through a security policy.

By default, the local VPN gateway is the IP address of the selected Local Interface. If you are configuring an interface mode VPN, you can optionally use a secondary IP address of the Local Interface as the local gateway.

## Choosing main mode or aggressive mode

The FortiGate unit and the remote peer or dialup client exchange phase 1 parameters in either Main mode or Aggressive mode. This choice does not apply if you use IKE version 2, which is available only for route-based configurations.

- In Main mode, the phase 1 parameters are exchanged in multiple rounds with encrypted authentication information
- In Aggressive mode, the phase 1 parameters are exchanged in single message with authentication information that is not encrypted.

Although Main mode is more secure, you must select Aggressive mode if there is more than one dialup phase 1 configuration for the interface IP address, and the remote VPN peer or client is authenticated using an identifier local ID). Descriptions of the peer options in this guide indicate whether Main or Aggressive mode is required.

# Choosing the IKE version

If you create a route-based VPN, you have the option of selecting IKE version 2. Otherwise, IKE version 1 is used.

IKEv2, defined in RFC 4306, simplifies the negotiation process that creates the security association (SA).

If you select IKEv2:

- There is no choice in Phase 1 of Aggressive or Main mode.
- FortiOS does not support Peer Options or Local ID.
- Extended Authentication (XAUTH) is not available.
- You can select only one DH Group.

# Authenticating the FortiGate unit

The FortiGate unit can authenticate itself to remote peers or dialup clients using either a pre-shared key or an RSA Signature (certificate).

## Authenticating the FortiGate unit with digital certificates

To authenticate the FortiGate unit using digital certificates, you must have the required certificates installed on the remote peer and on the FortiGate unit. The signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer. If you use certificates to authenticate the FortiGate unit, you can also require the remote peers or dialup clients to authenticate using certificates.

For more information about obtaining and installing certificates, see the [FortiOS User Authentication guide](#).

### To authenticate the FortiGate unit using digital certificates

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Create a new phase 1 configuration or edit an existing phase 1 configuration.
3. Include appropriate entries as follows:

<b>Name</b>	Enter a name that reflects the origination of the remote connection. For interface mode, the name can be up to 15 characters long.
<b>Remote Gateway</b>	Select the nature of the remote connection.  Each option changes the available fields you must configure. For more information, see <a href="#">“Defining the tunnel ends” on page 1638</a> .
<b>Local Interface</b>	Select the interface that is the local end of the IPsec tunnel. For more information, see <a href="#">“Defining the tunnel ends” on page 1638</a> . The local interface is typically the WAN1 port.

<b>Mode</b>	<p>Select a mode. It is easier to use aggressive mode.</p> <ul style="list-style-type: none"> <li>• In Main mode, parameters are exchanged in multiple encrypted rounds.</li> <li>• In Aggressive mode, parameters are exchanged in a single unencrypted message.</li> </ul> <p>Aggressive mode must be used when the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID).</p> <p>For more information, see <a href="#">“Choosing main mode or aggressive mode” on page 1638</a>.</p>
<b>Authentication Method</b>	Select <i>RSA Signature</i> .
<b>Certificate Name</b>	<p>Select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during phase 1 negotiations.</p> <p>You must obtain and load the required server certificate before this selection. See the <a href="#">FortiOS User Authentication guide</a>. If you have not loaded any certificates, use the certificate named <i>Fortinet_Factory</i>.</p>
<b>Peer Options</b>	<p>Peer options define the authentication requirements for remote peers or dialup clients. They are not for your FortiGate unit itself.</p> <p>See <a href="#">“Authenticating remote peers and clients” on page 1642</a>.</p>
<b>Advanced</b>	<p>You can use the default settings for most phase 1 configurations. Changes are required only if your network requires them. These settings includes IKE version, DNS server, P1 proposal encryption and authentication settings, and XAuth settings. See <a href="#">“Defining IKE negotiation parameters” on page 1646</a>.</p>

4. If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters in the Advanced section. See [“Using the FortiGate unit as an XAuth server” on page 1651](#).
5. Select OK.

## Authenticating the FortiGate unit with a pre-shared key

The simplest way to authenticate a FortiGate unit to its remote peers or dialup clients is by means of a pre-shared key. This is less secure than using certificates, especially if it is used alone, without requiring peer IDs or extended authentication (XAuth). Also, you need to have a secure way to distribute the pre-shared key to the peers.

If you use pre-shared key authentication alone, all remote peers and dialup clients must be configured with the same pre-shared key. Optionally, you can configure remote peers and dialup clients with unique pre-shared keys. On the FortiGate unit, these are configured in user accounts, not in the phase\_1 settings. For more information, see [“Enabling VPN access with user accounts and pre-shared keys” on page 1645](#).

The pre-shared key must contain at least 6 printable characters and best practices dictate that it be known only to network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.

If you authenticate the FortiGate unit using a pre-shared key, you can require remote peers or dialup clients to authenticate using peer IDs, but not client certificates.

### To authenticate the FortiGate unit with a pre-shared key

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Create a new phase 1 configuration or edit an existing phase 1 configuration.
3. Include appropriate entries as follows:

<b>Name</b>	Enter a name that reflects the origination of the remote connection.
<b>Remote Gateway</b>	Select the nature of the remote connection. For more information, see <a href="#">“Defining the tunnel ends” on page 1638</a> .
<b>Local Interface</b>	Select the interface that is the local end of the IPsec tunnel. For more information, see <a href="#">“Defining the tunnel ends” on page 1638</a> . The local interface is typically the WAN1 port.
<b>Mode</b>	<p>Select Main or Aggressive mode.</p> <ul style="list-style-type: none"><li>• In Main mode, the phase 1 parameters are exchanged in multiple rounds with encrypted authentication information.</li><li>• In Aggressive mode, the phase 1 parameters are exchanged in single message with authentication information that is not encrypted.</li></ul> <p>When the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID), you must select Aggressive mode if there is more than one dialup phase 1 configuration for the interface IP address.</p> <p>For more information, see <a href="#">“Choosing main mode or aggressive mode” on page 1638</a>.</p>
<b>Authentication Method</b>	Select <i>Pre-shared Key</i> .
<b>Pre-shared Key</b>	Enter the preshared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during phase 1 negotiations. You must define the same value at the remote peer or client. The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.
<b>Peer options</b>	Peer options define the authentication requirements for remote peers or dialup clients, not for the FortiGate unit itself. You can require the use of peer IDs, but not client certificates. For more information, see <a href="#">“Authenticating remote peers and clients” on page 1642</a> .
<b>Advanced</b>	You can retain the default settings unless changes are needed to meet your specific requirements. See <a href="#">“Defining IKE negotiation parameters” on page 1646</a> .

4. If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters. See [“Using the FortiGate unit as an XAuth server” on page 1651](#).
5. Select *OK*.

## Authenticating remote peers and clients

Certificates or pre-shared keys restrict who can access the VPN tunnel, but they do not identify or authenticate the remote peers or dialup clients. You have the following options for authentication:

**Table 73:** Methods of authenticating remote VPN peers

Certificates or Pre-shared key	Local ID	User account pre-shared keys	Reference
Certificates			See <a href="#">“Enabling VPN access for specific certificate holders”</a> on page 1642
Either	<b>X</b>		See <a href="#">“Enabling VPN access by peer identifier”</a> on page 1644
Pre-shared key		<b>X</b>	See <a href="#">“Enabling VPN access with user accounts and pre-shared keys”</a> on page 1645
Pre-shared key	<b>X</b>	<b>X</b>	See <a href="#">“Enabling VPN access with user accounts and pre-shared keys”</a> on page 1645

For authentication of users of the remote peer or dialup client device, see [“Using XAuth authentication”](#) on page 1650.

### Enabling VPN access for specific certificate holders

When a VPN peer or dialup client is configured to authenticate using digital certificates, it sends the DN of its certificate to the FortiGate unit. This DN can be used to allow VPN access for the certificate holder. That is, a FortiGate unit can be configured to deny connections to all remote peers and dialup clients except the one having the specified DN.

#### Before you begin

The following procedures assume that you already have an existing phase 1 configuration (see [“Authenticating the FortiGate unit with digital certificates”](#) on page 1639). Follow the procedures below to add certificate-based authentication parameters to the existing configuration.

Before you begin, you must obtain the certificate DN of the remote peer or dialup client. If you are using the FortiClient application as a dialup client, refer to [FortiClient online Help](#) for information about how to view the certificate DN. To view the certificate DN of a FortiGate unit, see [“To view server certificate information and obtain the local DN”](#) on page 1643.

Use the `config user peer` CLI command to load the DN value into the FortiGate configuration. For example, if a remote VPN peer uses server certificates issued by your own organization, you would enter information similar to the following:

```
config user peer
  edit DN_FG1000
    set cn 192.168.2.160
    set cn-type ipv4
  end
```

The value that you specify to identify the entry (for example, DN\_FG1000) is displayed in the Accept this peer certificate only list in the IPsec phase 1 configuration when you return to the web-based manager.

If the remote VPN peer has a CA-issued certificate to support a higher level of credibility, you would enter information similar to the following:

```
config user peer
  edit CA_FG1000
    set ca CA_Cert_1
    set subject FG1000_at_site1
  end
```

The value that you specify to identify the entry (for example, CA\_FG1000) is displayed in the Accept this peer certificate only list in the IPsec phase 1 configuration when you return to the web-based manager. For more information about these CLI commands, see the “user” chapter of the [FortiGate CLI Reference](#).

A group of certificate holders can be created based on existing user accounts for dialup clients. To create the user accounts for dialup clients, see the “User” chapter of the [FortiGate Administration Guide](#). To create the certificate group afterward, use the `config user peergrp` CLI command. See the “user” chapter of the [FortiGate CLI Reference](#).

#### To view server certificate information and obtain the local DN

1. Go to *System > Certificates > Local Certificates*.
2. Note the CN value in the *Subject* field (for example, CN = 172.16.10.125, CN = info@fortinet.com, or CN = www.example.com).

#### To view CA root certificate information and obtain the CA certificate name

1. Go to *System > Certificates > CA Certificates*.
2. Note the value in the *Name* column (for example, CA\_Cert\_1).

### Configuring certificate authentication for a VPN

With peer certificates loaded, peer users and peer groups defined, you can configure your VPN to authenticate users by certificate.

#### To enable access for a specific certificate holder or a group of certificate holders

1. At the FortiGate VPN server, go to *VPN > IPsec > Auto Key (IKE)*.
2. In the list of defined configurations, select the phase 1 configuration and edit it.
3. From the *Authentication Method* list, select *RSA Signature*.
4. From the *Certificate Name* list, select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client.
5. Under *Peer Options*, select one of these options:
  - To accept a specific certificate holder, select *Accept this peer certificate only* and select the name of the certificate that belongs to the remote peer or dialup client. The certificate DN must be added to the FortiGate configuration through CLI commands before it can be selected here. See [“Before you begin” on page 1642](#).
  - To accept dialup clients who are members of a certificate group, select *Accept this peer certificate group only* and select the name of the group. The group must be added to the FortiGate configuration through CLI commands before it can be selected here. See [“Before you begin” on page 1642](#).
6. If you want the FortiGate VPN server to supply the DN of a local server certificate for authentication purposes, select *Advanced* and then from the *Local ID* list, select the DN of the certificate that the FortiGate VPN server is to use.
7. Select *OK*.

## Enabling VPN access by peer identifier

Whether you use certificates or pre-shared keys to authenticate the FortiGate unit, you can require that remote peers or clients have a particular peer ID. This adds another piece of information that is required to gain access to the VPN. More than one FortiGate/FortiClient dialup client may connect through the same VPN tunnel when the dialup clients share a preshared key and assume the same identifier.

A peer ID, also called local ID, can be up to 63 characters long containing standard regular expression characters. Local ID is set in phase1 Aggressive Mode configuration.

You cannot require a peer ID for a remote peer or client that uses a pre-shared key and has a static IP address.

### To authenticate remote peers or dialup clients using one peer ID

1. At the FortiGate VPN server, go to *VPN > IPsec > Auto Key (IKE)*.
2. In the list, select a phase 1 configuration and edit its parameters.
3. Select *Aggressive* mode in any of the following cases:
  - the FortiGate VPN server authenticates a FortiGate dialup client that uses a dedicated tunnel
  - a FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service
  - FortiGate/FortiClient dialup clients sharing the same preshared key and local ID connect through the same VPN tunnel
4. Select *Accept this peer ID* and type the identifier into the corresponding field.
5. Select *OK*.

### To assign an identifier (local ID) to a FortiGate unit

Use this procedure to assign a peer ID to a FortiGate unit that acts as a remote peer or dialup client.

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. In the list, select a phase 1 configuration and edit its parameters.
3. Select *Advanced*.
4. In the *Local ID* field, type the identifier that the FortiGate unit will use to identify itself.
5. Set *Mode* to *Aggressive* if any of the following conditions apply:
  - The FortiGate unit is a dialup client that will use a unique ID to connect to a FortiGate dialup server through a dedicated tunnel.
  - The FortiGate unit has a dynamic IP address, subscribes to a dynamic DNS service, and will use a unique ID to connect to the remote VPN peer through a dedicated tunnel.
  - The FortiGate unit is a dialup client that shares the specified ID with multiple dialup clients to connect to a FortiGate dialup server through the same tunnel.
6. Select *OK*.

### To configure the FortiClient application

Follow this procedure to add a peer ID to an existing FortiClient configuration:

1. Start the FortiClient application.
2. Go to *VPN > Connections*, select the existing configuration.
3. Select *Advanced > Edit > Advanced*.
4. Under *Policy*, select *Config*.

5. In the *Local ID* field, type the identifier that will be shared by all dialup clients. This value must match the *Accept this peer ID* value that you specified previously in the phase 1 gateway configuration on the FortiGate unit.
6. Select *OK* to close all dialog boxes.
7. Configure all dialup clients the same way using the same preshared key and local ID.

## Enabling VPN access with user accounts and pre-shared keys

You can permit access only to remote peers or dialup clients that have pre-shared keys and/or peer IDs configured in user accounts on the FortiGate unit.

If you want two VPN peers (or a FortiGate unit and a dialup client) to accept reciprocal connections based on peer IDs, you must enable the exchange of their identifiers when you define the phase 1 parameters.

The following procedures assume that you already have an existing phase 1 configuration (see [“Authenticating the FortiGate unit with digital certificates” on page 1639](#)). Follow the procedures below to add ID checking to the existing configuration.

Before you begin, you must obtain the identifier (local ID) of the remote peer or dialup client. If you are using the FortiClient Endpoint Security application as a dialup client, refer to the [Authenticating FortiClient Dialup Clients Technical Note](#) to view or assign an identifier. To assign an identifier to a FortiGate dialup client or a FortiGate unit that has a dynamic IP address and subscribes to a dynamic DNS service, see [“To assign an identifier \(local ID\) to a FortiGate unit” on page 1644](#).

If required, a dialup user group can be created from existing user accounts for dialup clients. To create the user accounts and user groups, see the [User Authentication](#) chapter of The Handbook.

The following procedure supports FortiGate/FortiClient dialup clients that use unique preshared keys and/or peer IDs. The client must have an account on the FortiGate unit and be a member of the dialup user group.

The dialup user group must be added to the FortiGate configuration before it can be selected. For more information, see the [User Authentication](#) chapter of The Handbook.

The FortiGate dialup server compares the local ID that you specify at each dialup client to the FortiGate user-account user name. The dialup-client preshared key is compared to a FortiGate user-account password.

### To authenticate dialup clients using unique preshared keys and/or peer IDs

- 1 At the FortiGate VPN server, go to *VPN > IPsec > Auto Key (IKE)*.
- 2 In the list, select the *Edit* icon of a phase 1 configuration to edit its parameters.
- 3 If the clients have unique peer IDs, set *Mode* to *Aggressive*.
- 4 Clear the *Pre-shared Key* field.  
The user account password will be used as the preshared key.
- 5 Select *Accept peer ID in dialup group* and then select the group name from the list of user groups.
- 6 Select *OK*.

Follow this procedure to add a unique pre-shared key and unique peer ID to an existing FortiClient configuration.

### To configure FortiClient - pre-shared key and peer ID

1. Start the FortiClient Endpoint Security application.
2. Go to *VPN > Connections*, select the existing configuration.

3. Select *Advanced > Edit*.
4. In the *Preshared Key* field, type the FortiGate password that belongs to the dialup client (for example, 1234546).  
The user account password will be used as the preshared key.
5. Select *Advanced*.
6. Under *Policy*, select *Config*.
7. In the *Local ID* field, type the FortiGate user name that you assigned previously to the dialup client (for example, FortiClient1).
8. Select *OK* to close all dialog boxes.

Configure all FortiClient dialup clients this way using unique preshared keys and local IDs.

Follow this procedure to add a unique pre-shared key to an existing FortiClient configuration.

#### **To configure FortiClient - preshared key only**

1. Start the FortiClient Endpoint Security application.
2. Go to *VPN > Connections*, select the existing configuration
3. Select *Advanced > Edit*.
4. In the *Preshared Key* field, type the user name, followed by a “+” sign, followed by the password that you specified previously in the user account settings on the FortiGate unit (for example, FC2+1FG6LK)
5. Select *OK* to close all dialog boxes.

Configure all the FortiClient dialup clients this way using their unique peer ID and pre-shared key values.

## **Defining IKE negotiation parameters**

In phase 1, the two peers exchange keys to establish a secure communication channel between them. As part of the phase 1 process, the two peers authenticate each other and negotiate a way to encrypt further communications for the duration of the session. For more information see [“Authenticating remote peers and clients” on page 1642](#). The P1 Proposal parameters select the encryption and authentication algorithms that are used to generate keys for protecting negotiations.

The IKE negotiation parameters determine:

- which encryption algorithms may be applied for converting messages into a form that only the intended recipient can read
- which authentication hash may be used for creating a keyed hash from a preshared or private key
- which Diffie-Hellman group (DH Group) will be used to generate a secret session key

Phase 1 negotiations (in main mode or aggressive mode) begin as soon as a remote VPN peer or client attempts to establish a connection with the FortiGate unit. Initially, the remote peer or dialup client sends the FortiGate unit a list of potential cryptographic parameters along with a session ID. The FortiGate unit compares those parameters to its own list of advanced phase 1 parameters and responds with its choice of matching parameters to use for authenticating and encrypting packets. The two peers handle the exchange of encryption keys between them, and authenticate the exchange through a preshared key or a digital signature.

## Generating keys to authenticate an exchange

The FortiGate unit supports the generation of secret session keys automatically using a Diffie-Hellman algorithm. These algorithms are defined in RFC 2409. The *Keylife* setting in the *P1 Proposal* area determines the amount of time before the phase 1 key expires. Phase 1 negotiations are rekeyed automatically when there is an active security association. See [“Dead peer detection” on page 1650](#).

You can enable or disable automatic rekeying between IKE peers through the `phase1-rekey` attribute of the `config system global` CLI command. For more information, see the “system” chapter of the [FortiGate CLI Reference](#).

When in FIPS-CC mode, the FortiGate unit requires DH key exchange to use values at least 3072 bits long. However most browsers need the key size set to 1024. You can set the minimum size of the DH keys in the CLI.

```
config system global
    set dh-params 3072
end
```

When you use a preshared key (shared secret) to set up two-party authentication, the remote VPN peer or client and the FortiGate unit must both be configured with the same preshared key. Each party uses a session key derived from the Diffie-Hellman exchange to create an authentication key, which is used to sign a known combination of inputs using an authentication algorithm (such as HMAC-MD5, HMAC-SHA-1, or HMAC-SHA-256). Hash-based Message Authentication Code (HMAC) is a method for calculating an authentication code using a hash function plus a secret key, and is defined in RFC 2104. Each party signs a different combination of inputs and the other party verifies that the same result can be computed.

SHA-256, SHA-384 and SHA-512 are not accelerated by some FortiASIC processors (including FortiASIC network processors and security processors). As a result, using SHA-256, SHA-384 and SHA-512 may reduce the performance of the FortiGate unit more significantly than SHA-1 which is accelerated by all FortiASIC processors.

When you use preshared keys to authenticate VPN peers or clients, you must distribute matching information to all VPN peers and/or clients whenever the preshared key changes.

As an alternative, the remote peer or dialup client and FortiGate unit can exchange digital signatures to validate each other's identity with respect to their public keys. In this case, the required digital certificates must be installed on the remote peer and on the FortiGate unit. By exchanging certificate DNs, the signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer.

The following procedure assumes that you already have a phase 1 definition that describes how remote VPN peers and clients will be authenticated when they attempt to connect to a local FortiGate unit. For information about the Local ID and XAuth options, see [“Enabling VPN access with user accounts and pre-shared keys” on page 1645](#) and [“Using the FortiGate unit as an XAuth server” on page 1651](#). Follow this procedure to add IKE negotiation parameters to the existing definition.

## Defining IKE negotiation parameters

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. In the list, select the *Edit* button to edit the phase 1 parameters for a particular remote gateway.

3. Select *Advanced* and include appropriate entries and select *OK*:

---

**P1 Proposal**

Select the encryption and authentication algorithms that will be used to generate keys for protecting negotiations.

Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define.

You can select any of these symmetric-key algorithms:

- DES-Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.
- 3DES-Triple-DES, in which plain text is encrypted three times by three keys.
- AES128-A 128-bit block algorithm that uses a 128-bit key.
- AES192-A 128-bit block algorithm that uses a 192-bit key.
- AES256-A 128-bit block algorithm that uses a 256-bit key.

You can select one of the following message digests to check the authenticity of messages during phase 1 negotiations:

- MD5-Message Digest 5, the hash algorithm developed by RSA Data Security.
- SHA1-Secure Hash Algorithm 1, which produces a 160-bit message digest.
- SHA-256 Secure Hash Algorithm 256, which produces a 256-bit message digest
- SHA-384 Secure Hash Algorithm 384, which produces a 384-bit message digest
- SHA-512 Secure Hash Algorithm 512, which produces a 512-bit message digest

To specify a third combination, use the add button beside the fields for the second combination.

SHA-256, SHA-384 and SHA-512 are not accelerated by some FortiASIC processors (including FortiASIC network processors and security processors). As a result, using SHA-256, SHA-384 and SHA-512 may reduce the performance of the FortiGate unit more significantly than SHA-1 which is accelerated by all FortiASIC processors.

---

<b>DH Group</b>	<p>Select one or more Diffie-Hellman groups from DH group 1, 2, and 5. When using aggressive mode, DH groups cannot be negotiated.</p> <p>If both VPN peers (or a VPN server and its client) have static IP addresses and use aggressive mode, select a single DH group. The setting on the FortiGate unit must be identical to the setting on the remote peer or dialup client.</p> <p>When the remote VPN peer or client has a dynamic IP address and uses aggressive mode, select up to three DH groups on the FortiGate unit and one DH group on the remote peer or dialup client. The setting on the remote peer or dialup client must be identical to one of the selections on the FortiGate unit.</p> <p>If the VPN peer or client employs main mode, you can select multiple DH groups. At least one of the settings on the remote peer or dialup client must be identical to the selections on the FortiGate unit.</p>
<b>Keylife</b>	<p>Type the amount of time (in seconds) that will be allowed to pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172800 seconds.</p>
<b>Nat-traversal</b>	<p>Enable this option if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared). When in doubt, enable NAT-traversal. See <a href="#">“NAT traversal” on page 1649</a>.</p>
<b>Keepalive Frequency</b>	<p>If you enabled NAT traversal, enter a keepalive frequency setting. The value represents an interval from 0 to 900 seconds where the connection will be maintained with no activity. For additional security this value must be as low as possible. See <a href="#">“NAT keepalive frequency” on page 1650</a>.</p>
<b>Dead Peer Detection</b>	<p>Enable this option to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. This feature minimizes the traffic required to check if a VPN peer is available or unavailable (dead). See <a href="#">“Dead peer detection” on page 1650</a>.</p>

## NAT traversal

Network Address Translation (NAT) is a way to convert private IP addresses to publicly routable Internet addresses and vice versa. When an IP packet passes through a NAT device, the source or destination address in the IP header is modified. FortiGate units support NAT version 1 (encapsulate on port 500 with non-IKE marker), version 3 (encapsulate on port 4500 with non-ESP marker), and compatible versions.

NAT cannot be performed on IPsec packets in ESP tunnel mode because the packets do not contain a port number. As a result, the packets cannot be demultiplexed. To work around this, the FortiGate unit provides a way to protect IPsec packet headers from NAT modifications. When the Nat-traversal option is enabled, outbound encrypted packets are wrapped inside a UDP IP header that contains a port number. This extra encapsulation allows NAT devices to change the port number without modifying the IPsec packet directly.

To provide the extra layer of encapsulation on IPsec packets, the Nat-traversal option must be enabled whenever a NAT device exists between two FortiGate VPN peers or a FortiGate unit and a dialup client such as FortiClient. On the receiving end, the FortiGate unit or FortiClient removes the extra layer of encapsulation before decrypting the packet.

## NAT keepalive frequency

When a NAT device performs network address translation on a flow of packets, the NAT device determines how long the new address will remain valid if the flow of traffic stops (for example, the connected VPN peer may be idle). The device may reclaim and reuse a NAT address when a connection remains idle for too long.

To work around this, when you enable NAT traversal specify how often the FortiGate unit sends periodic keepalive packets through the NAT device in order to ensure that the NAT address mapping does not change during the lifetime of a session. To be effective, the keepalive interval must be smaller than the session lifetime value used by the NAT device.

The keepalive packet is a 138-byte ISAKMP exchange.

## Dead peer detection

Sometimes, due to routing issues or other difficulties, the communication link between a FortiGate unit and a VPN peer or client may go down. Packets could be lost if the connection is left to time out on its own. The FortiGate unit provides a mechanism called Dead Peer Detection, sometimes referred to as gateway detection or ping server, to prevent this situation and reestablish IKE negotiations automatically before a connection times out: the active phase 1 security associations are caught and renegotiated (rekeyed) before the phase 1 encryption key expires.

By default, Dead Peer Detection sends probe messages every five seconds by default (see `dpd-retryinterval` in the [FortiGate CLI Reference](#)). If you are experiencing high network traffic, you can experiment with increasing the ping interval. However longer intervals will require more traffic to detect dead peers which will result in more traffic.

In the web-based manager, the Dead Peer Detection option can be enabled when you define advanced phase 1 options. The `config vpn ipsec phase1` CLI command supports additional options for specifying a retry count and a retry interval.

For more information about these commands and the related `config router gwdetect` CLI command, see the [FortiGate CLI Reference](#).

For example, enter the following CLI commands to configure dead peer detection on the existing IPsec Phase1 configuration called `test` to use 15 second intervals and to wait for 3 missed attempts before declaring the peer dead and taking action.

```
config vpn ipsec phase1
  edit test
    set dpd enable
    set dpd-retryinterval 15
    set dpd-retrycount 3
  next
end
```

## Using XAuth authentication

Extended authentication (XAuth) increases security by requiring the remote dialup client user to authenticate in a separate exchange at the end of phase 1. XAuth draws on existing FortiGate user group definitions and uses established authentication mechanisms such as PAP, CHAP, RADIUS and LDAP to authenticate dialup clients. You can configure a FortiGate unit to function either as an XAuth server or an XAuth client. If the server or client is attempting a connection using XAuth and the other end is not using XAuth, the failed connection attempts that are logged will not specify XAuth as the reason.

## Using the FortiGate unit as an XAuth server

A FortiGate unit can act as an XAuth server for dialup clients. When the phase 1 negotiation completes, the FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.

If the user records on the RADIUS server have suitably configured Framed-IP-Address fields, you can assign client virtual IP addresses by XAuth instead of from a DHCP address range. See [“Assigning VIPs by RADIUS user group” on page 1713](#).

The authentication protocol to use for XAuth depends on the capabilities of the authentication server and the XAuth client:

- Select PAP whenever possible.
- You must select PAP for all implementations of LDAP and some implementations of Microsoft RADIUS.
- Select AUTO when the authentication server supports CHAP but the XAuth client does not. The FortiGate unit will use PAP to communicate with the XAuth client and CHAP to communicate with the authentication server.

Before you begin, create user accounts and user groups to identify the dialup clients that need to access the network behind the FortiGate dialup server. If password protection will be provided through an external RADIUS or LDAP server, you must configure the FortiGate dialup server to forward authentication requests to the authentication server. For information about these topics, see the [FortiGate User Authentication Guide](#).

### To authenticate a dialup user group using XAuth settings

1. At the FortiGate dialup server, go to *VPN > IPsec > Auto Key (IKE)*.
2. In the list, select the *Edit* icon of a phase 1 configuration to edit its parameters for a particular remote gateway.
3. Select *Advanced*.
4. Under *XAuth*, select *Enable as Server*.
5. The *Server Type* setting determines the type of encryption method to use between the XAuth client, the FortiGate unit and the authentication server. Select one of the following options:
  - *PAP*—Password Authentication Protocol.
  - *CHAP*—Challenge-Handshake Authentication Protocol.
  - *AUTO*—Use PAP between the XAuth client and the FortiGate unit, and CHAP between the FortiGate unit and the authentication server.
6. From the *User Group* list, select the user group that needs to access the private network behind the FortiGate unit. The group must be added to the FortiGate configuration before it can be selected here.
7. Select *OK*.

## Using the FortiGate unit as an XAuth client

If the FortiGate unit acts as a dialup client, the remote peer, acting as an XAuth server, might require a user name and password. You can configure the FortiGate unit as an XAuth client, with its own user name and password, which it provides when challenged.

### To configure the FortiGate dialup client as an XAuth client

1. At the FortiGate dialup client, go to *VPN > IPsec > Auto Key (IKE)*.
2. In the list, select a phase 1 configuration and select *Edit*.
3. Select *Advanced*.

4. Under *XAuth*, select *Enable as Client*.
5. In the *Username* field, type the FortiGate PAP, CHAP, RADIUS, or LDAP user name that the FortiGate XAuth server will compare to its records when the FortiGate XAuth client attempts to connect.
6. In the *Password* field, type the password to associate with the user name.
7. Select *OK*.

# Phase 2 parameters

This section describes the phase 2 parameters that are required to establish communication through a VPN.

The following topics are included in this section:

- [Basic phase 2 settings](#)
- [Advanced phase 2 settings](#)
- [Configure the phase 2 parameters](#)

## Basic phase 2 settings

After IPsec VPN phase 1 negotiations complete successfully, phase 2 negotiation begins. Phase 2 parameters define the algorithms that the FortiGate unit can use to encrypt and transfer data for the remainder of the session. The basic phase 2 settings associate IPsec phase 2 parameters with a phase 1 configuration.

When defining phase 2 parameters, you can choose any set of phase 1 parameters to set up a secure connection and authenticate the remote peer.

For more information on phase 2 settings in the web-based manager, see [“Phase 2 configuration” on page 1629](#)

## Advanced phase 2 settings

The following additional advanced phase 2 settings are available to enhance the operation of the tunnel:

- [P2 Proposals](#)
- [Replay detection](#)
- [Perfect forward secrecy \(PFS\)](#)
- [Keylife](#)
- [Quick mode selectors](#)

### P2 Proposals

In phase 2, the VPN peer or client and the FortiGate unit exchange keys again to establish a secure communication channel. The P2 Proposal parameters select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). The keys are generated automatically using a Diffie-Hellman algorithm.

### Replay detection

IPsec tunnels can be vulnerable to replay attacks. Replay detection enables the FortiGate unit to check all IPsec packets to see if they have been received before. If any encrypted packets arrive out of order, the FortiGate unit discards them.

## Perfect forward secrecy (PFS)

By default, phase 2 keys are derived from the session key created in phase 1. Perfect forward secrecy forces a new Diffie-Hellman exchange when the tunnel starts and whenever the phase 2 keylife expires, causing a new key to be generated each time. This exchange ensures that the keys created in phase 2 are unrelated to the phase 1 keys or any other keys generated automatically in phase 2.

## Keylife

The Keylife setting sets a limit on the length of time that a phase 2 key can be used. The default units are seconds. Alternatively, you can set a limit on the number of kilobytes (KB) of processed data, or both. If you select both, the key expires when either the time has passed or the number of KB have been processed. When the phase 2 key expires, a new key is generated without interrupting service.

## Auto-negotiate

By default, the phase 2 security association (SA) is not negotiated until a peer attempts to send data. The triggering packet and some subsequent packets are dropped until the SA is established. Applications normally resend this data, so there is no loss, but there might be a noticeable delay in response to the user.

Automatically establishing the SA can also be important for a dialup peer. This ensures that the VPN tunnel is available for peers at the server end to initiate traffic to the dialup peer. Otherwise, the VPN tunnel does not exist until the dialup peer initiates traffic.

When enabled, auto-negotiate initiates the phase 2 SA negotiation automatically, repeating every five seconds until the SA is established.

The auto-negotiate feature is available only through the Command Line Interface (CLI). Use the following commands to enable it.

```
config vpn ipsec phase2
    edit <phase2_name>
        set auto-negotiate enable
    end
```

If the tunnel goes down, the auto-negotiate feature will attempt to re-establish it. However, the Autokey Keep Alive feature is a better method to ensure your VPN remains up.

## Autokey Keep Alive

The phase 2 SA has a fixed duration. If there is traffic on the VPN as the SA nears expiry, a new SA is negotiated and the VPN switches to the new SA without interruption. If there is no traffic, the SA expires and the VPN tunnel goes down. A new SA will not be generated until there is traffic.

The Autokey Keep Alive option ensures that a new SA is negotiated even if there is no traffic so that the VPN tunnel stays up.

## DHCP-IPsec

Select this option if the FortiGate unit assigns VIP addresses to FortiClient dialup clients through a DHCP server or relay. This option is available only if the Remote Gateway in the phase 1 configuration is set to Dialup User and it works only on policy-based VPNs.

With the DHCP-IPsec option, the FortiGate dialup server acts as a proxy for FortiClient dialup clients that have VIP addresses on the subnet of the private network behind the FortiGate unit. In this case, the FortiGate dialup server acts as a proxy on the local private network for the FortiClient dialup client. When a host on the network behind the dialup server issues an ARP request that corresponds to the device MAC address of the FortiClient host (when a remote server sends an ARP to the local FortiClient dialup client), the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel.

This feature prevents the VIP address assigned to the FortiClient dialup client from causing possible arp broadcast problems — the normal and VIP addresses can confuse some network switches by two addresses having the same MAC address.

## Quick mode selectors

Quick Mode selectors determine which IP addresses can perform IKE negotiations to establish a tunnel. By only allowing authorized IP addresses access to the VPN tunnel, the network is more secure.

The default settings are as broad as possible: any IP address or configured address object, using any protocol, on any port.

While the drop down menus for specifying an address also show address groups, the use of address groups is not supported.

To make it easy to determine if one of the choices in the drop down menu is an address or an address group the two types of objects have been broken into sections with the address groups at the bottom of the list.

---

When configuring Quick Mode selector *Source Address* and *Destination address*, valid options include IPv4 and IPv6 single addresses, IPv4 subnet, or IPv6 subnet. For more information on IPv6 IPsec VPN, see [“Overview of IPv6 IPsec support” on page 1772](#).

There are some configurations that require specific selectors:

- the VPN peer is a third-party device that uses specific phase2 selectors
- the FortiGate unit connects as a dialup client to another FortiGate unit, in which case you must specify a source IP address, IP address range or subnet

With FortiOS VPNs, your network has multiple layers of security, with quick mode selectors being an important line of defence.

- Routes guide traffic from one IP address to another.
- Phase 1 and phase 2 connection settings ensure there is a valid remote end point for the VPN tunnel that agrees on the encryption and parameters.
- Quick mode selectors allow IKE negotiations only for allowed peers.
- Security policies control which IP addresses can connect to the VPN.
- Security policies also control what protocols are allowed over the VPN along with any bandwidth limiting.

## Configure the phase 2 parameters

If you are creating a hub-and-spoke configuration or an Internet-browsing configuration, you may have already started defining some of the required phase 2 parameters. If so, edit the existing definition to complete the configuration.

## Specifying the phase 2 parameters

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 2*.
3. Enter a *Name* for the phase 2 configuration, and select a *Phase 1* configuration from the drop-down list.
4. Select *Advanced*.
5. Include appropriate entries and select *OK*:

<b>P2 Proposal</b>	<p>Select the encryption and authentication algorithms that will be used to change data into encrypted code.</p> <p>Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define.</p> <p>It is invalid to set both <i>Encryption</i> and <i>Authentication</i> to null.</p>
<b>Encryption</b>	<p>Select a symmetric-key algorithms:</p> <p><b>NULL</b> — Do not use an encryption algorithm.</p> <p><b>DES</b> — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key.</p> <p><b>3DES</b> — Triple-DES; plain text is encrypted three times by three keys.</p> <p><b>AES128</b> — A 128-bit block algorithm that uses a 128-bit key.</p> <p><b>AES192</b> — A 128-bit block algorithm that uses a 192-bit key.</p> <p><b>AES256</b> — A 128-bit block algorithm that uses a 256-bit key.</p>
<b>Authentication</b>	<p>You can select either of the following message digests to check the authenticity of messages during an encrypted session:</p> <ul style="list-style-type: none"><li>• <b>NULL</b> — Do not use a message digest.</li><li>• <b>MD5</b> — Message Digest 5.</li><li>• <b>SHA1</b> — Secure Hash Algorithm 1 - a 160-bit message digest.</li></ul> <p>To specify one combination only, set the <i>Encryption</i> and <i>Authentication</i> options of the second combination to NULL. To specify a third combination, use the <i>Add</i> button beside the fields for the second combination.</p>
<b>Enable replay detection</b>	<p>Optionally enable or disable replay detection. Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.</p>
<b>Enable perfect forward secrecy (PFS)</b>	<p>Enable or disable PFS. Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.</p>
<b>DH Group</b>	<p>Select one Diffie-Hellman group (1, 2, 5, or 14). The remote peer or dialup client must be configured to use the same group.</p>

<b>Keylife</b>	Select the method for determining when the phase 2 key expires: <i>Seconds</i> , <i>KBytes</i> , or <i>Both</i> . If you select <i>Both</i> , the key expires when either the time has passed or the number of KB have been processed. The range is from 120 to 172800 seconds, or from 5120 to 2147483648 KB.
<b>Autokey Keep Alive</b>	Enable the option if you want the tunnel to remain active when no data is being processed.
<b>DHCP-IPsec</b>	<p>Select <i>Enable</i> if the FortiGate unit acts as a dialup server and FortiGate DHCP server or relay will be used to assign VIP addresses to FortiClient dialup clients. The DHCP server or relay parameters must be configured separately.</p> <p>If the FortiGate unit acts as a dialup server and the FortiClient dialup client VIP addresses match the network behind the dialup server, select <i>Enable</i> to cause the FortiGate unit to act as a proxy for the dialup clients.</p> <p>This is available only for phase 2 configurations associated with a dialup phase 1 configuration. It works only on policy-based VPNs.</p>
<b>Quick Mode Selector</b>	<p>Optionally specify the source and destination IP address to be used as selectors for IKE negotiations. If the FortiGate unit is a dialup server, keep the default value 0.0.0.0/0 unless you need to circumvent problems caused by ambiguous IP addresses between one or more of the private networks making up the VPN.</p> <p>Note that IKEv1 does not support the use of multiple addresses in selectors. Instead, use the default 0.0.0.0/0 subnet selector and rely on the firewall policy to limit destination addresses. Only use the Addressing objects if they are carried over from earlier versions of FortiOS.</p> <p>If you are editing an existing phase 2 configuration, the <i>Source address</i> and <i>Destination address</i> fields are unavailable if the tunnel has been configured to use firewall addresses as selectors. This option exists only in the CLI. See the <i>dst-addr-type</i>, <i>dst-name</i>, <i>src-addr-type</i> and <i>src-name</i> keywords for the <code>vpn ipsec phase2</code> command in the <a href="#">FortiGate CLI Reference</a>.</p>
<b>Source address</b>	<p>If the FortiGate unit is a dialup server, type the source IP address that corresponds to the local sender(s) or network behind the local VPN peer (for example, 172.16.5.0/24 or 172.16.5.0/255.255.255.0 for a subnet, or 172.16.5.1/32 or 172.16.5.1/255.255.255.255 for a server or host, or 192.168.10.[80-100] or 192.168.10.80-192.168.10.100 for an address range). A value of 0.0.0.0/0 means all IP addresses behind the local VPN peer.</p> <p>If the FortiGate unit is a dialup client, source address must refer to the private network behind the FortiGate dialup client.</p>
<b>Source port</b>	Type the port number that the local VPN peer uses to transport traffic related to the specified service (protocol number). The range is 0 to 65535. To specify all ports, type 0.

<b>Destination address</b>	Type the destination IP address that corresponds to the recipient(s) or network behind the remote VPN peer (for example, 192.168.20.0/24 for a subnet, or 172.16.5.1/32 for a server or host, or 192.168.10.[80-100] for an address range). A value of 0.0.0.0/0 means all IP addresses behind the remote VPN peer.
<b>Destination port</b>	Type the port number that the remote VPN peer uses to transport traffic related to the specified service (protocol number). The range is 0 to 65535. To specify all ports, type 0.
<b>Protocol</b>	Type the IP protocol number of the service. The range is 1 to 255. To specify all services, type 0.

# Defining VPN security policies

This section explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN, and how to define appropriate security policies.

The following topics are included in this section:

- [Defining policy addresses](#)
- [Defining VPN security policies](#)

## Defining policy addresses

A VPN tunnel has two end points. These end points may be VPN peers such as two FortiGate gateways. Encrypted packets are transmitted between the end points. At each end of the VPN tunnel, a VPN peer intercepts encrypted packets, decrypts the packets, and forwards the decrypted IP packets to the intended destination.

You need to define firewall addresses for the private networks behind each peer. You will use these addresses as the source or destination address depending on the security policy.

**Figure 253:**Example topology for the following policies

In general:

- In a gateway-to-gateway, hub-and-spoke, dynamic DNS, redundant-tunnel, or transparent configuration, you need to define a policy address for the private IP address of the network behind the remote VPN peer (for example, 192.168.10.0/255.255.255.0 or 192.168.10.0/24).
- In a peer-to-peer configuration, you need to define a policy address for the private IP address of a server or host behind the remote VPN peer (for example, 172.16.5.1/255.255.255.255 or 172.16.5.1/32 or 172.16.5.1).

For a FortiGate dialup server in a dialup-client or Internet-browsing configuration:

- If you are not using VIP addresses, or if the FortiGate dialup server assigns VIP addresses to FortiClient dialup clients through FortiGate DHCP relay, select the predefined destination address “all” in the security policy to refer to the dialup clients.
- If you assign VIP addresses to FortiClient dialup clients manually, you need to define a policy address for the VIP address assigned to the dialup client (for example, 10.254.254.1/32), or a subnet address from which the VIP addresses are assigned (for example, 10.254.254.0/24 or 10.254.254.0/255.255.255.0).
- For a FortiGate dialup client in a dialup-client or Internet-browsing configuration, you need to define a policy address for the private IP address of a host, server, or network behind the FortiGate dialup server.

#### To define a security IP address

1. Go to *Firewall Objects > Address > Addresses* and select *Create New*.
2. In the *Name* field, type a descriptive name that represents the network, server(s), or host(s).
3. In *Type*, select *Subnet*.
4. In the *Subnet/IP Range* field, type the corresponding IP address and subnet mask.  
For a subnet you could use the format 172.16.5.0/24 or its equivalent 172.16.5.0/255.255.255.0. For a server or host it would likely be 172.16.5.1/32. Alternately you can use an IP address range such as 192.168.10.[80-100] or 192.168.10.80-192.168.10.100.
5. Select *OK*.

## Defining VPN security policies

Security policies allow IP traffic to pass between interfaces on a FortiGate unit. You can limit communication to particular traffic by specifying source address and destination addresses. Then only traffic from those addresses will be allowed.

Policy-based and route-based VPNs require different security policies.

- A policy-based VPN requires an IPsec security policy. You specify the interface to the private network, the interface to the remote peer and the VPN tunnel. A single policy can enable traffic inbound, outbound, or in both directions.
- A route-based VPN requires an Accept security policy for each direction. As source and destination interfaces, you specify the interface to the private network and the virtual IPsec interface (phase 1 configuration) of the VPN. The IPsec interface is the destination interface for the outbound policy and the source interface for the inbound policy. One security policy must be configured for each direction of each VPN interface.

There are examples of security policies for both policy-based and route-based VPNs throughout this guide. See [“Route-based or policy-based VPN” on page 1697](#).

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won't be able to retrieve a lease from the FortiGate's (IPSec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

---

## Defining an IPsec security policy for a policy-based VPN

An IPsec security policy enables the transmission and reception of encrypted packets, specifies the permitted direction of VPN traffic, and selects the VPN tunnel. In most cases, a single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel.

### Allow traffic to be initiated from the remote site

In addition to these operations, security policies specify which IP addresses can initiate a tunnel. By default, traffic from the local private network initiates the tunnel. When the *Allow traffic to be initiated from the remote site* option is selected, traffic from a dialup client or computers on the remote network initiates the tunnel. Both can be enabled at the same time for bi-directional initiation of the tunnel.

### Outbound and inbound NAT

When a FortiGate unit operates in NAT mode, you can also enable inbound or outbound NAT. Outbound NAT may be performed on outbound encrypted packets, or on IP packets before they are sent through the tunnel. Inbound NAT is performed on IP packets emerging from the tunnel. By default, these options are not selected in security policies.

When used in conjunction with the `natip` CLI attribute (see the “config firewall” chapter of the [FortiGate CLI Reference](#)), outbound NAT enables you to change the source addresses of IP packets before they go into the tunnel. This feature is often used to resolve ambiguous routing when two or more of the private networks making up a VPN have the same or overlapping IP addresses.

When inbound NAT is enabled, inbound encrypted packets are intercepted and decrypted, and the source IP addresses of the decrypted packets are translated into the IP address of the FortiGate interface to the local private network before they are routed to the private network. If the computers on the local private network can communicate only with devices on the local private network (that is, the FortiGate interface to the private network is not the default gateway) and the remote client (or remote private network) does not have an IP address in the same network address space as the local private network, enable inbound NAT.

### Source and destination addresses

Most security policies control outbound IP traffic. A VPN outbound policy usually has a source address originating on the private network behind the local FortiGate unit, and a destination address belonging to a dialup VPN client or a network behind the remote VPN peer. The source address that you choose for the security policy identifies from where outbound cleartext IP packets may originate, and also defines the local IP address or addresses that a remote server or client will be allowed to access through the VPN tunnel. The destination address that you choose identifies where IP packets must be forwarded after they are decrypted at the far end of the tunnel, and determines the IP address or addresses that the local network will be able to access at the far end of the tunnel.

### Enabling other policy features

You can fine-tune a policy for services such as HTTP, FTP, and POP3; enable logging, traffic shaping, antivirus protection, web filtering, email filtering, file transfer, and email services throughout the VPN; and optionally allow connections according to a predefined schedule.

As an option, differentiated services (diffserv or DSCP) can be enabled in the security policy through CLI commands. For more information on this feature, see [Traffic Shaping chapter](#) or the “firewall” chapter of the [FortiGate CLI Reference](#).

When a remote server or client attempts to connect to the private network behind a FortiGate gateway, the security policy intercepts the connection attempt and starts the VPN tunnel. The

FortiGate unit uses the remote gateway specified in its phase 1 tunnel configuration to reply to the remote peer. When the remote peer receives a reply, it checks its own security policy, including the tunnel configuration, to determine which communications are permitted. As long as one or more services are allowed through the VPN tunnel, the two peers begin to negotiate the tunnel. To follow this negotiation in the web-based manager, go to *VPN > Monitor > IPsec Monitor*. There you will find a list of the VPN tunnels, their status, and the data flow both incoming and outgoing.

## Before you begin

Before you define the IPsec policy, you must:

- Define the IP source and destination addresses. See [“Defining policy addresses” on page 1659](#).
- Specify the phase 1 authentication parameters. See [“Auto Key phase 1 parameters” on page 1637](#).
- Specify the phase 2 parameters. See [“Phase 2 parameters” on page 1653](#).

### To define an IPsec security policy

1. Go to *Policy > Policy > Policy*.
2. Select *Create New* and select *VPN*.
3. Complete the options:

<b>Local Interface</b>	Select the local interface to the internal (private) network.
<b>Local Protected Subnet</b>	Select the name that corresponds to the local network, server(s), or host(s) from which IP packets may originate.
<b>Outgoing VPN Interface</b>	Select the local interface to the external (public) network.
<b>Remote Protected Subnet</b>	Select the name that corresponds to the remote network, server(s), or host(s) to which IP packets may be delivered.
<b>Schedule</b>	Keep the default setting (always) unless changes are needed to meet specific requirements.
<b>Service</b>	Keep the default setting (ANY) unless changes are needed to meet your specific requirements.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the tunnel from the drop-down list.
<b>Allow traffic to be initiated from the remote site</b>	Select if traffic from the remote network will be allowed to initiate the tunnel.

4. You may enable UTM features, and/or event logging, or select advanced settings to authenticate a user group, or shape traffic. For more information, see the [Firewall](#) chapter of [The Handbook](#).
5. Select *OK*.
6. Place the policy in the policy list above any other policies having similar source and destination addresses.

## Defining multiple IPsec policies for the same tunnel

You must define at least one IPsec policy for each VPN tunnel. If the same remote server or client requires access to more than one network behind a local FortiGate unit, the FortiGate unit

must be configured with an IPsec policy for each network. Multiple policies may be required to configure redundant connections to a remote destination or control access to different services at different times.

To ensure a secure connection, the FortiGate unit must evaluate IPSEC policies before ACCEPT and DENY security policies. Because the FortiGate unit reads policies starting at the top of the list, you must move all IPsec policies to the top of the list. When you define multiple IPsec policies for the same tunnel, you must reorder the IPsec policies that apply to the tunnel so that specific constraints can be evaluated before general constraints.

Adding multiple IPsec policies for the same VPN tunnel can cause conflicts if the policies specify similar source and destination addresses but have different settings for the same service. When policies overlap in this manner, the system may apply the wrong IPsec policy or the tunnel may fail.

---

For example, if you create two equivalent IPsec policies for two different tunnels, it does not matter which one comes first in the list of IPsec policies — the system will select the correct policy based on the specified source and destination addresses. If you create two different IPsec policies for the same tunnel (that is, the two policies treat traffic differently depending on the nature of the connection request), you might have to reorder the IPsec policies to ensure that the system selects the correct IPsec policy. Reordering is especially important when the source and destination addresses in both policies are similar (for example, if one policy specifies a subset of the IP addresses in another policy). In this case, place the IPsec policy having the most specific constraints at the top of the list so that it can be evaluated first.

## Defining security policies for a route-based VPN

When you define a route-based VPN, you create a virtual IPsec interface on the physical interface that connects to the remote peer. You create ordinary Accept security policies to enable traffic between the IPsec interface and the interface that connects to the private network. This makes configuration simpler than for policy-based VPNs, which require IPsec security policies.

### To define security policies for a route-based VPN

1. Go to *Policy > Policy > Policy*.
2. Select *Create New* and leave the *Policy Type* as *Firewall*, and the *Policy Subtype* as *Address*.

3. Define an **ACCEPT** security policy to permit communications between the local private network and the private network behind the remote peer. Enter these settings in particular:

<b>Incoming Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Source Address</b>	Select the address name that you defined for the private network behind this FortiGate unit.
<b>Outgoing Interface</b>	Select the IPsec Interface you configured.
<b>Destination Address</b>	Select the address name that you defined for the private network behind the remote peer.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable.

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

4. Select *Create New* and leave the *Policy Type* as *Firewall*, and the *Policy Subtype* as *Address*
5. Enter these settings in particular:

<b>Incoming Interface</b>	Select the IPsec Interface you configured.
<b>Source Address</b>	Select the address name that you defined for the private network behind the remote peer.
<b>Outgoing Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Destination Address</b>	Select the address name that you defined for the private network behind this FortiGate unit.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable.

# Gateway-to-gateway configurations

This section explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN.

The following topics are included in this section:

- [Configuration overview](#)
- [General configuration steps](#)
- [Configuring the two VPN peers](#)
- [How to work with overlapping subnets](#)
- [Testing](#)

## Configuration overview

In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks. All traffic between the two networks is encrypted and protected by FortiGate security policies.

**Figure 254:**Example gateway-to-gateway configuration

In some cases, computers on the private network behind one VPN peer may (by co-incidence) have IP addresses that are already used by computers on the network behind the other VPN peer. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent. To resolve issues related to ambiguous routing, see [“How to work with overlapping subnets” on page 1672](#).

In other cases, computers on the private network behind one VPN peer may obtain IP addresses from a local DHCP server. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and/or IP-address overlap issues may arise. For a discussion of the related issues, see [“FortiGate dialup-client configurations” on page 1724](#).

You can set up a fully meshed or partially meshed configuration (see [Figure 255](#) and [Figure 256](#)).

**Figure 255:** Fully meshed configuration

In a fully meshed network, all VPN peers are connected to each other, with one hop between peers. This topology is the most fault-tolerant: if one peer goes down, the rest of the network is not affected. This topology is difficult to scale because it requires connections between all peers. In addition, unnecessary communication can occur between peers. Best practices dictates a hub-and-spoke configuration instead (see [“Hub-and-spoke configurations” on page 1679](#)).

**Figure 256:** Partially meshed configuration

A partially meshed network is similar to a fully meshed network, but instead of having tunnels between all peers, tunnels are only configured between peers that communicate with each other regularly.

## General configuration steps

The FortiGate units at both ends of the tunnel must be operating in NAT mode and have static public IP addresses.

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec phase 1 parameters to establish a secure connection and authenticate that VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec phase 2 parameters and applies the IPsec security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed by both FortiGate units:

- Define the phase 1 parameters that the FortiGate unit needs to authenticate the remote peer and establish a secure connection.
- Define the phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with the remote peer.
- Create security policies to control the permitted services and permitted direction of traffic between the IP source and destination addresses.

### Using auto-ipsec

In some cases, it may be easier to use the `auto-ipsec` CLI command to notify and push the IPsec configuration to the branch offices. For more information, refer to the [FortiGate CLI Reference](#).

## Configuring the two VPN peers

Configure the VPN peers as follows. Each step is required, but these are general steps. For more detailed information on each step follow the cross references. See [“Auto Key phase 1 parameters” on page 1637](#). All steps are required. Cross references point to required information that is repeated. No steps are optional.

### Configuring Phase 1 and Phase 2 for both peers

This procedure applies to both peers. Repeat the procedure on each FortiGate unit, using the correct IP address for each. You may wish to vary the Phase 1 names but this is optional. Otherwise all steps are the same for each peer.

The phase 1 configuration defines the parameters that FortiGate\_1 will use to authenticate FortiGate\_2 and establish a secure connection. For the purposes of this example, a preshared key will be used to authenticate FortiGate\_2. The same preshared key must be specified at both FortiGate units.

Before you define the phase 1 parameters, you need to:

- Reserve a name for the remote gateway.
- Obtain the IP address of the public interface to the remote peer.
- Reserve a unique value for the preshared key.

The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must have a minimum of 16 randomly chosen alphanumeric characters.

At the local FortiGate unit, define the phase 1 configuration needed to establish a secure connection with the remote peer. See [“Phase 1 configuration” on page 1625](#).

### To create phase 1 to establish a secure connection with the remote peer

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 1*.
3. Enter the following information, and select *OK*.

<b>Name</b>	Enter <code>peer_1</code> .  A name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies and the VPN monitor.
<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Enter <code>172.20.0.2</code> when configuring FortiGate_1. Enter <code>172.18.0.2</code> when configuring FortiGate_2. The IP address of the remote peer public interface.
<b>Local Interface</b>	Select <i>wan1</i> .
<b>Enable IPsec Interface Mode</b>	Select <i>Advanced</i> to see this setting.  Enable <i>IPsec Interface Mode</i> to have the FortiGate unit create a virtual IPsec interface for a route-based VPN.  Disable this option to create a policy-based VPN. For more information, see <a href="#">“Comparing policy-based or route-based VPNs” on page 1621</a> .  After selecting <i>OK</i> , you cannot change this setting.

The basic phase 2 settings associate IPsec phase 2 parameters with the phase 1 configuration and specify the remote end point of the VPN tunnel. Before you define the phase 2 parameters, you need to reserve a name for the tunnel. See [“Phase 2 configuration” on page 1629](#).

### To configure phase 2 settings

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 2*.
3. Enter a *Name* of `peer_1_p2`.
4. Select *peer\_1* from the *Phase 1* drop-down menu.

## Creating security policies

Security policies control all IP traffic passing between a source address and a destination address.

An IPsec security policy is needed to allow the transmission of encrypted packets, specify the permitted direction of VPN traffic, and select the VPN tunnel that will be subject to the policy. A single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel.

Before you define security policies, you must first specify the IP source and destination addresses. In a gateway-to-gateway configuration:

- The IP source address corresponds to the private network behind the local FortiGate unit.
- The IP destination address refers to the private network behind the remote VPN peer.

When you are creating security policies, choose one of either route-based or policy-based methods and follow it for both VPN peers. DO NOT configure both route-based and policy-based policies on the same FortiGate unit for the same VPN tunnel.

The configuration of FortiGate\_2 is similar to that of FortiGate\_1. You must:

- Define the phase 1 parameters that FortiGate\_2 needs to authenticate FortiGate\_1 and establish a secure connection.
- Define the phase 2 parameters that FortiGate\_2 needs to create a VPN tunnel with FortiGate\_1.
- Create the security policy and define the scope of permitted services between the IP source and destination addresses.

When creating security policies it is good practice to include a comment describing what the policy does.

When creating security policies you need to be

- [Creating firewall addresses](#)
- [Creating route-based VPN security policies](#)
- [Configuring a default route for VPN interface](#)

or

- [Creating firewall addresses](#)
- [Creating policy-based VPN security policy](#)

## Creating firewall addresses

Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks.

### To define the IP address of the network behind FortiGate\_1

1. Go to *Firewall Objects > Address > Addresses* and select *Create New*.
2. Enter the *Name* of `Finance_network`.
3. Select a *Type* of *Subnet*.
4. Enter the *Subnet* of `10.21.101.0/24`.
5. Select *OK*.

### To specify the address of the network behind FortiGate\_2

1. Go to *Firewall Objects > Address > Addresses* and select *Create New*.
2. Enter the *Name* of `HR_network`.
3. Select a *Type* of *Subnet*.
4. Enter the *Subnet/IP Range* of `10.31.101.0/24`.
5. Select *OK*.

## Creating route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

### To create route-based VPN security policies

1. Go to *Policy > Policy > Policy* and select *Create New*
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following, and select *OK*.

<b>Incoming Interface</b>	Select <i>internal</i> .  The interface that connects to the private network behind this FortiGate unit.
<b>Source Address</b>	Select <i>Finance_network</i> when configuring FortiGate_1. Select <i>HR_network</i> when configuring FortiGate_2.  The address name for the private network behind this FortiGate unit.
<b>Outgoing Interface</b>	Select <i>peer_1</i> .  The VPN Tunnel (IPsec Interface) you configured earlier.
<b>Destination Address</b>	Select <i>HR_network</i> when configuring FortiGate_1. Select <i>Finance_network</i> when configuring FortiGate_2.  The address name that you defined for the private network behind the remote peer.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable.
<b>Comments</b>	Allow Internal to remote VPN network traffic.

4. Configure any additional features such as UTM or traffic shaping you may want. (optional).
5. Select *Create New* to create another policy for the other direction.
6. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
7. Enter the following information, and select *OK*.

<b>Incoming Interface</b>	Select <i>peer_1</i> .  The VPN Tunnel (IPsec Interface) you configured.
<b>Source Address</b>	Select <i>HR_network</i> when configuring FortiGate_1. Select <i>Finance_Network</i> when configuring FortiGate_2.  The address name defined for the private network behind the remote peer.
<b>Outgoing Interface</b>	Select <i>internal</i> .  The interface that connects to the private network behind this FortiGate unit.
<b>Destination Address</b>	Select <i>Finance_Network</i> when configuring FortiGate_1. Select <i>HR_network</i> when configuring FortiGate_2.  The address name defined for the private network behind this FortiGate unit.

<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable.
<b>Comments</b>	Allow remote VPN network traffic to Internal.

8. Configure any additional features such as UTM or traffic shaping you may want. (optional).

### Configuring a default route for VPN interface

All network traffic must have a static route to direct its traffic to the proper destination. Without a route, traffic will not flow even if the security policies are configured properly. You may need to create a static route entry for both directions of VPN traffic if your security policies allow bi-directional tunnel initiation.

#### To configure the route for a route-based VPN

1. On FortiGate\_2, go to *Router > Static > Static Routes* and select *Create New*.  
For low-end FortiGate units, go to *System > Network > Routing* and select *Create New*.
2. Enter the following information, and then select *OK*:

<b>Destination IP / Mask</b>	10.21.101.0/24
<b>Device</b>	FGT2_to_FGT1_Tunnel
<b>Gateway</b>	Leave as default: 0.0.0.0.
<b>Distance (Advanced)</b>	Leave this at its default.  If there are other routes on this FortiGate unit, you may need to set the distance on this route so the VPN traffic will use it as the default route. However, this normally happens by default because this route is typically a better match than the generic default route.

### Creating policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to *Policy > Policy > Policy*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Complete the following:

<b>Local Interface</b>	Select <i>internal</i> .  The interface that connects to the private network behind this FortiGate unit.
<b>Local Protected Subnet</b>	Select <i>Finance_network</i> when configuring FortiGate_1. Select <i>HR_network</i> when configuring FortiGate_2.  The address name defined for the private network behind this FortiGate unit.
<b>Outgoing VPN Interface</b>	Select <i>wan1</i> .  The FortiGate unit's public interface.

<b>Remote Protected Subnet</b>	Select <i>HR_network</i> when configuring FortiGate_1.
	Select <i>Finance_network</i> when configuring FortiGate_2.
	The address name that you defined in Step for the private network behind the remote peer.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select <i>peer_1</i> from the <i>VPN Tunnel</i> drop-down list.
	Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.
<b>Comments</b>	Bidirectional policy-based VPN policy.

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

## How to work with overlapping subnets

A site-to-site VPN configuration sometimes has the problem that the private subnet addresses at each end are the same. You can resolve this problem by remapping the private addresses using virtual IP addresses (VIP).

VIPs allow computers on those overlapping private subnets to each have another set of IP addresses that can be used without confusion. The FortiGate unit maps the VIP addresses to the original addresses. This means if PC1 starts a session with PC2 at 10.31.101.10, FortiGate\_2 directs that session to 10.11.101.10 — the actual IP address of PC2. [Figure 257](#) shows this — Finance network VIP is 10.21.101.0/24 and the HR network is 10.31.101.0/24.

**Figure 257:**Overlapped subnets example

## Solution for route-based VPN

You need to:

- Configure IPsec Phase 1 and Phase 2 as you usually would for a route-based VPN. In this example, the resulting IPsec interface is named `FGT1_to_FGT2`.
- Configure virtual IP (VIP) mapping:
  - the 10.21.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate\_1
  - the 10.31.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate\_2
- Configure an outgoing security policy with ordinary source NAT on both FortiGates.
- Configure an incoming security policy with the VIP as the destination on both FortiGates.
- Configure a route to the remote private network over the IPsec interface on both FortiGates.

### To configure VIP mapping on both FortiGates

1. Go to *Firewall Objects > Virtual IPs > Virtual IPs* and select *Create New*.
2. Enter the following information, and select *OK*:

<b>Name</b>	Enter a name, for example, <code>my_vip</code> .
<b>External Interface</b>	Select <code>FGT1_to_FGT2</code> . The IPsec interface.
<b>Type</b>	Static NAT
<b>External IP Address/Range</b>	For the external IP address field enter: <ul style="list-style-type: none"><li>• <code>10.21.101.1</code> when configuring FortiGate_1, or</li><li>• <code>10.31.101.1</code> when configuring FortiGate_2.</li></ul>
<b>Mapped IP Address/Range</b>	For the Mapped IP Address enter <code>10.11.101.1</code> . For the Range enter <code>10.11.101.254</code> .
<b>Port Forwarding</b>	Disable

Repeat this procedure on both FortiGate\_1 and FortiGate\_2.

### To configure the outbound security policy on both FortiGates

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Select <i>Port 1</i> .
<b>Source Address</b>	Select <i>all</i> .
<b>Outgoing Interface</b>	Select <code>FGT1_to_FGT2</code> . The IPsec interface.
<b>Destination Address</b>	Select <i>all</i> .
<b>Action</b>	Select <i>ACCEPT</i>
<b>Enable NAT</b>	Enable

Repeat this procedure on both FortiGate\_1 and FortiGate\_2.

### To configure the inbound security policy on both FortiGates

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and then select *OK*:

<b>Incoming Interface</b>	Select <i>FGT1_to_FGT2</i> .
<b>Source Address</b>	Select <i>all</i> .
<b>Outgoing Interface</b>	Select <i>Port 1</i> . The IPsec interface.
<b>Destination Address</b>	Select <i>my-vip</i> .
<b>Action</b>	Select <i>ACCEPT</i>
<b>Enable NAT</b>	Disable

Repeat this procedure on both FortiGate\_1 and FortiGate\_2.

### To configure the static route for both FortiGates

1. Go to *Router > Static > Static Routes* and select *Create New*.  
For low-end FortiGate units, go to *System > Network > Routing* and select *Create New*.
2. Enter the following information, and then select *OK*:

<b>Destination IP / Mask</b>	Enter <i>10.31.101.0/24</i> when configuring FortiGate_1. Enter <i>10.21.101.0/24</i> when configuring FortiGate_2.
<b>Device</b>	Select <i>FGT1_to_FGT2</i> .
<b>Gateway</b>	Leave as default: <i>0.0.0.0</i> .
<b>Distance (Advanced)</b>	Leave at default. If you have advanced routing on your network, you may have to change this value

## Solution for policy-based VPN

As with the route-based solution, users contact hosts at the other end of the VPN using an alternate subnet address. PC1 communicates with PC2 using IP address 10.31.101.10, and PC2 communicates with PC1 using IP address 10.21.101.10.

In this solution however, outbound NAT is used to translate the source address of packets from the 10.11.101.0/24 network to the alternate subnet address that hosts at the other end of the VPN use to reply. Inbound packets from the remote end have their destination addresses translated back to the 10.11.101.0/24 network.

For example, PC1 uses the destination address 10.31.101.10 to contact PC2. Outbound NAT on FortiGate\_1 translates the PC1 source address to 10.21.101.10. At the FortiGate\_2 end of the tunnel, the outbound NAT configuration translates the destination address to the actual PC2 address of 10.11.101.10. Similarly, PC2 replies to PC1 using destination address 10.21.101.10,

with the PC2 source address translated to 10.31.101.10. PC1 and PC2 can communicate over the VPN even though they both have the same IP address.

- You need to:
- Configure IPsec Phase 1 as you usually would for a policy-based VPN.
- Configure IPsec Phase 2 with the `use-natip disable` CLI option.
- Define a firewall address for the local private network, 10.11.101.0/24.
- Define a firewall address for the remote private network:
  - define a firewall address for 10.31.101.0/24 on FortiGate\_1
  - define a firewall address for 10.21.101.0/24 on FortiGate\_2
- Configure an outgoing IPsec security policy with outbound NAT to map 10.11.101.0/24 source addresses:
  - to the 10.21.101.0/24 network on FortiGate\_1
  - to the 10.31.101.0/24 network on FortiGate\_2

### To configure IPsec Phase 2 - CLI

```
config vpn ipsec phase2
  edit "FGT1_FGT2_p2"
    set keepalive enable
    set pfs enable
    set phase1name FGT1_to_FGT2
    set proposal 3des-sha1 3des-md5
    set replay enable
    set use-natip disable
  end
```

In this example, your phase 1 definition is named FGT1\_to\_FGT2. `use-natip` is set to `disable`, so you can specify the source selector using the `src-addr-type`, `src-start-ip` / `src-end-ip` or `src-subnet` keywords. This example leaves these keywords at their default values, which specify the subnet 0.0.0.0/0.

The `pfs` keyword ensures that perfect forward secrecy (PFS) is used. This ensures that each Phase 2 key created is unrelated to any other keys in use.

### To define the local private network firewall address

1. Go to *Firewall Objects > Address > Addresses* and select *Create New*.
2. Enter the following information and select *OK*.

<b>Name</b>	Enter <code>vpn-local</code> . A meaningful name for the local private network.
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	10.11.101.0 255.255.255.0
<b>Interface</b>	Any

### To define the remote private network firewall address

1. Go to *Firewall Objects > Address > Addresses* and select *Create New*.

2. Enter the following information, and select *OK*:

<b>Name</b>	Enter <code>vpn-remote</code> . A meaningful name for the remote private network.
<b>Type</b>	Subnet
<b>Subnet / IP Range</b>	10.31.101.0 255.255.255.0 on FortiGate_1. 10.21.101.0 255.255.255.0 on FortiGate_2.
<b>Interface</b>	Any

### To configure the IPsec security policy

In the CLI on FortiGate\_1, enter the commands:

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "vpn-local"
    set dstaddr "vpn-remote"
    set action ipsec
    set schedule "always"
    set service "ANY"
    set inbound enable
    set outbound enable
    set vpntunnel "FGT1_to_FGT2"
    set natoutbound enable
    set natip 10.31.101.0 255.255.255.0
  end
```

Optionally, you can set everything except `natip` in the web-based manager and then use the CLI to set `natip`.

Enter the same commands on FortiGate\_2, but set `natip` be `10.21.101.0 255.255.255.0`.

## Testing

The best testing is to look at the packets both as the VPN tunnel is negotiated, and when the tunnel is up.

### To determine what the other end of the VPN tunnel is proposing

1. Start a terminal program such as `puTTY` and set it to log all output.  
When necessary refer to the logs to locate information when output is verbose.
2. Logon to the FortiGate unit using a `super_admin` account.
3. Enter the following CLI commands.
4. Display all the possible IKE error types and the number of times they have occurred:  
`diag vpn ike errors`

5. Check for existing debug sessions:  
`diag debug info`  
 If a debug session is running, to halt it enter:  
`diag debug disable`
6. Confirm your proposal settings:  
`diag vpn ike config list`
7. If your proposal settings do not match what you expect, make a change to it and save it to force an update in memory. If that fixes the problem, stop here.
8. List the current vpn filter:  
`diag vpn ike filter`
9. If all fields are set to any, there are no filters set and all VPN ike packets will be displayed in the debug output. If your system has only a few VPNs, skip setting the filter.  
 If your system has many VPN connections this will result in very verbose output and make it very difficult to locate the correct connection attempt.
10. Set the VPN filter to display only information from the destination IP address for example 10.10.10.10:  
`diag vpn ike log-filter dst-addr4 10.10.10.10`  
 To add more filter options, enter them one per line as above. Other filter options are:

<b>clear</b>	<b>erase the current filter</b>
dst-addr6	the IPv6 destination address range to filter by
dst-port	the destination port range to filter by
interface	interface that IKE connection is negotiated over
list	display the current filter
name	the phase1 name to filter by
negate	negate the specified filter parameter
src-addr4	the IPv4 source address range to filter by
src-addr6	the IPv6 source address range to filter by
src-port	the source port range to filter by
vd	index of virtual domain. 0 matches all

11. Start debugging:  
`diag debug app ike 255`  
`diag debug enable`
12. Have the remote end attempt a VPN connection.  
 If the remote end attempts the connection they become the initiator. This situation makes it easier to debug VPN tunnels because then you have the remote information and all of your local information. by initiate the connection, you will not see the other end's information.
13. If possible go to the web-based manager on your FortiGate unit, go to the VPN monitor and try to bring the tunnel up.
14. Stop the debug output:  
`diag debug disable`

- 15.** Go back through the output to determine what proposal information the initiator is using, and how it is different from your VPN P1 proposal settings.

Things to look for in the debug output of attempted VPN connections are shown below.

**Table 74:** Important terms to look for in VPN debug output

initiator	Starts the VPN attempt, in the above procedure that is the remote end
responder	Answers the initiator's request
local ID	In aggressive mode, this is not encrypted
error no SA proposal chosen	There was no proposal match — there was no encryption-authentication pair in common, usually occurs after a long list of proposal attempts
R U THERE and R U THERE ack	dead peer detection (dpd), also known as dead gateway detection — after three failed attempts to contact the remote end it will be declared dead, no farther attempts will be made to contact it
negotiation result	lists the proposal settings that were agreed on
SA_life_soft and SA_life_hard	negotiating a new key, and the key life
R U THERE	If you see this, it means Phase 1 was successful
tunnel up	the negotiation was successful, the VPN tunnel is operational

# Hub-and-spoke configurations

This section describes how to set up hub-and-spoke IPsec VPNs. The following topics are included in this section:

- [Configuration overview](#)
- [Configure the hub](#)
- [Configure the spokes](#)
- [Dynamic spokes configuration example](#)

## Configuration overview

In a hub-and-spoke configuration, VPN connections radiate from a central FortiGate unit (the hub) to a number of remote peers (the spokes). Traffic can pass between private networks behind the hub and private networks behind the remote peers. Traffic can also pass between remote peer private networks through the hub.

**Figure 258:**Example hub-and-spoke configuration

The actual implementation varies in complexity depending on

- whether the spokes are statically or dynamically addressed
- the addressing scheme of the protected subnets
- how peers are authenticated.

This guide discusses the issues involved in configuring a hub-and-spoke VPN and provides some basic configuration examples.

## Hub-and-spoke infrastructure requirements

- The FortiGate hub must be operating in NAT mode and have a static public IP address.
- Spokes may have static IP addresses, dynamic IP addresses (see [“FortiGate dialup-client configurations” on page 1724](#)), or static domain names and dynamic IP addresses (see [“Dynamic DNS configuration” on page 1695](#)).

## Spoke gateway addressing

The public IP address of the spoke is the VPN remote gateway as seen from the hub. Statically addressed spokes each require a separate VPN phase 1 configuration on the hub. When there are many spokes, this becomes rather cumbersome.

Using dynamic addressing for spokes simplifies the VPN configuration because then the hub requires only a single phase 1 configuration with “dialup user” as the remote gateway. You can use this configuration even if the remote peers have static IP addresses. A remote peer can establish a VPN connection regardless of its IP address if its traffic selectors match and it can authenticate to the hub. See [“Dynamic spokes configuration example” on page 1689](#) for an example of this configuration.

## Protected networks addressing

The addresses of the protected networks are needed to configure destination selectors and sometimes for security policies and static routes. The larger the number of spokes, the more addresses there are to manage. You can

- assign spoke subnets as part of a larger subnet, usually on a new network or
- create address groups that contain all of the needed addresses

## Using aggregated subnets

If you are creating a new network, where subnet IP addresses are not already assigned, you can simplify the VPN configuration by assigning spoke subnets that are part of a large subnet.

**Figure 259:**Aggregated subnets

All spokes use the large subnet address, 10.1.0.0/16 for example, as

- the IPsec destination selector
- the destination of the security policy from the private subnet to the VPN (required for policy-based VPN, optional for route-based VPN)
- the destination of the static route to the VPN (route-based)

Each spoke uses the address of its own protected subnet as the IPsec source selector and as the source address in its VPN security policy. The remote gateway is the public IP address of the hub FortiGate unit.

## Using an address group

If you want to create a hub-and-spoke VPN between existing private networks, the subnet addressing usually does not fit the aggregated subnet model discussed earlier. All of the spokes and the hub will need to include the addresses of all the protected networks in their configuration.

On FortiGate units, you can define a named firewall address for each of the remote protected networks and add these addresses to a firewall address group. For a policy-based VPN, you can then use this address group as the destination of the VPN security policy.

For a route-based VPN, the destination of the VPN security policy can be set to All. You need to specify appropriate routes for each of the remote subnets.

## Authentication

Authentication is by a common preshared key or by certificates. For simplicity, the examples in this chapter assume that all spokes use the same preshared key.

## Configure the hub

At the FortiGate unit that acts as the hub, you need to

- configure the VPN to each spoke
- configure communication between spokes

You configure communication between spokes differently for a policy-based VPN than for a route-based VPN. For a policy-based VPN, you configure a VPN concentrator. For a route-based VPN, you must either define security policies or group the IPsec interfaces into a zone

## Define the hub-spoke VPNs

Perform these steps at the FortiGate unit that will act as the hub. Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

### To configure the VPN hub

1. At the hub, define the phase 1 configuration for each spoke. See [“Auto Key phase 1 parameters” on page 1637](#). Enter these settings in particular:

---

<b>Name</b>	Enter a name to identify the VPN in phase 2 configurations, security policies and the VPN monitor.
-------------	--

---

<b>Remote Gateway</b>	<p>The remote gateway is the other end of the VPN tunnel. There are three options:</p> <p><b>Static IP Address</b> — Enter the spoke's public <i>IP Address</i>. You will need to create a phase 1 configuration for each spoke. Either the hub or the spoke can establish the VPN connection.</p> <p><b>Dialup User</b> — No additional information is needed. The hub accepts connections from peers with appropriate encryption and authentication settings. Only one phase 1 configuration is needed for multiple dialup spokes. Only the spoke can establish the VPN tunnel.</p> <p><b>Dynamic DNS</b> — If the spoke subscribes to a dynamic DNS service, enter the spoke's <i>Dynamic DNS</i> domain name. Either the hub or the spoke can establish the VPN connection. For more information, see <a href="#">“Dynamic DNS configuration” on page 1695</a>.</p>
<b>Local Interface</b>	Select the FortiGate interface that connects to the remote gateway. This is usually the FortiGate unit's public interface.
<b>Enable IPsec Interface Mode</b>	<p>You must select Advanced to see this setting. If <i>IPsec Interface Mode</i> is enabled, the FortiGate unit creates a virtual IPsec interface for a route-based VPN. Disable this option if you want to create a policy-based VPN. For more information, see <a href="#">“Comparing policy-based or route-based VPNs” on page 1621</a>.</p> <p>After you select OK to create the phase 1 configuration, you cannot change this setting.</p>

2. Define the phase 2 parameters needed to create a VPN tunnel with each spoke. See [“Phase 2 parameters” on page 1653](#). Enter these settings in particular:

<b>Name</b>	Enter a name to identify this spoke phase 2 configuration.
<b>Phase 1</b>	Select the name of the phase 1 configuration that you defined for this spoke.

## Define the hub-spoke security policies

1. Define a name for the address of the private network behind the hub. For more information, see [“Defining policy addresses” on page 1659](#).
2. Define names for the addresses or address ranges of the private networks behind the spokes. For more information, see [“Defining policy addresses” on page 1659](#).
3. Define the VPN concentrator. See [“To define the VPN concentrator” on page 1684](#).
4. Define security policies to permit communication between the hub and the spokes. For more information, see [“Defining VPN security policies” on page 1660](#).

## Route-based VPN security policies

Define ACCEPT security policies to permit communications between the hub and the spoke. You need one policy for each direction.

### To add policies

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

3. Enter these settings in particular:

<b>Incoming Interface</b>	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
<b>Source Address</b>	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
<b>Outgoing Interface</b>	Select the hub's interface to the internal (private) network.
<b>Destination Address</b>	Select the source address that you defined in Step 1.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Enable.

<b>Incoming Interface</b>	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
<b>Source Address</b>	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate units.
<b>Outgoing Interface</b>	Select the source address that you defined in Step 1.
<b>Destination Address</b>	Select the hub's interface to the internal (private) network.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Enable.

### Policy-based VPN security policy

Define an IPsec security policy to permit communications between the hub and the spoke.

#### To add policies

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter these settings in particular:

<b>Local Interface</b>	Select the hub's interface to the internal (private) network.
<b>Local Protected Subnet</b>	Select the source address that you defined in Step 1.
<b>Outgoing VPN Interface</b>	Select the hub's public network interface.
<b>Remote Protected Subnet</b>	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the name of the phase 1 configuration that you created for the spoke in Step 1.  Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.

In the policy list, arrange the policies in the following order:

- IPsec policies that control traffic between the hub and the spokes first
- the default security policy last

## Configuring communication between spokes (policy-based VPN)

For a policy-based hub-and-spoke VPN, you define a concentrator to enable communication between the spokes.

### To define the VPN concentrator

1. At the hub, go to *VPN > IPSEC > Concentrator* and select *Create New*.
2. In the *Concentrator Name* field, type a name to identify the concentrator.
3. From the *Available Tunnels* list, select a VPN tunnel and then select the right-pointing arrow.
4. Repeat Step 3 until all of the tunnels associated with the spokes are included in the concentrator.
5. Select *OK*.

## Configuring communication between spokes (route-based VPN)

For a route-based hub-and-spoke VPN, there are several ways you can enable communication between the spokes:

- put all of the IPsec interfaces into a zone and enable intra-zone traffic. This eliminates the need for any security policy for the VPN, but you cannot apply UTM features to scan the traffic for security threats.
- put all of the IPsec interfaces into a zone and create a single zone-to-zone security policy
- create a security policy for each pair of spokes that are allowed to communicate with each other. The number of policies required increases rapidly as the number of spokes increases.

### Using a zone as a concentrator

A simple way to provide communication among all of the spokes is to create a zone and allow intra-zone communication. You cannot apply UTM features using this method.

1. Go to *System > Network > Interfaces*.
2. Select the down-arrow on the *Create New* button and select *Zone*.
3. In the *Zone Name* field, enter a name, such as `Our_VPN_zone`.
4. Clear *Block intra-zone traffic*.
5. In the *Interface Members* list, select the IPsec interfaces that are part of your VPN.
6. Select *OK*.

### Using a zone with a policy as a concentrator

If you put all of the hub IPsec interfaces involved in the VPN into a zone, you can enable communication among all of the spokes and apply UTM features with just one security policy.

### To create a zone for the VPN

1. Go to *System > Network > Interfaces*.
2. Select the down-arrow on the *Create New* button and select *Zone*.
3. In the *Zone Name* field, enter a name, such as `Our_VPN_zone`.
4. Select *Block intra-zone traffic*.

5. In the *Interface Members* list, select the IPsec interfaces that are part of your VPN.
6. Select *OK*.

#### To create a security policy for the zone

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the settings: and select *OK*.

<b>Incoming Interface</b>	Select the zone you created for your VPN.
<b>Source Address</b>	Select <i>All</i> .
<b>Outgoing Interface</b>	Select the zone you created for your VPN.
<b>Destination Address</b>	Select <i>All</i> .
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Enable.

### Using security policies as a concentrator

To enable communication between two spokes, you need to define an *ACCEPT* security policy for them. To allow either spoke to initiate communication, you must create a policy for each direction. This procedure describes a security policy for communication from Spoke 1 to Spoke 2. Others are similar.

1. Define names for the addresses or address ranges of the private networks behind each spoke. For more information, see [“Defining policy addresses” on page 1659](#).
2. Go to *Policy > Policy > Policy* and select *Create New*.
3. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
4. Enter the settings and select *OK*.

<b>Incoming Interface</b>	Select the IPsec interface that connects to Spoke 1.
<b>Source Address</b>	Select the address of the private network behind Spoke 1.
<b>Outgoing Interface</b>	Select the IPsec interface that connects to Spoke 2.
<b>Destination Address</b>	Select the address of the private network behind Spoke 2.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Enable.

## Configure the spokes

Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

Perform these steps at each FortiGate unit that will act as a spoke.

### To create the phase 1 and phase\_2 configurations

1. At the spoke, define the phase 1 parameters that the spoke will use to establish a secure connection with the hub. See [“Auto Key phase 1 parameters” on page 1637](#). Enter these settings:

<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Type the IP address of the interface that connects to the hub.
<b>Enable IPsec Interface Mode</b>	Enable if you are creating a route-based VPN. Clear if you are creating a policy-based VPN

2. Create the phase 2 tunnel definition. See [“Phase 2 parameters” on page 1653](#). Select the set of phase 1 parameters that you defined for the hub. You can select the name of the hub from the *Static IP Address* part of the list.

## Configuring security policies for hub-to-spoke communication

1. Create an address for this spoke. See [“Defining policy addresses” on page 1659](#). Enter the IP address and netmask of the private network behind the spoke.
2. Create an address to represent the hub. See [“Defining policy addresses” on page 1659](#). Enter the IP address and netmask of the private network behind the hub.
3. Define the security policy to enable communication with the hub.

### Route-based VPN security policy

Define two security policies to permit communications to and from the hub.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter these settings:

<b>Incoming Interface</b>	Select the virtual IPsec interface you created.
<b>Source Address</b>	Select the hub address you defined in Step 1.
<b>Outgoing Interface</b>	Select the spoke’s interface to the internal (private) network.
<b>Destination Address</b>	Select the spoke addresses you defined in Step 2.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Enable

<b>Incoming Interface</b>	Select the spoke’s interface to the internal (private) network.
<b>Source Address</b>	Select the spoke address you defined in Step 1.
<b>Outgoing Interface</b>	Select the virtual IPsec interface you created.
<b>Destination Address</b>	Select the hub destination addresses you defined in Step 2.

<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Enable

### Policy-based VPN security policy

Define an IPsec security policy to permit communications with the hub. See [“Defining VPN security policies” on page 1660](#).

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter these settings in particular:

<b>Local Interface</b>	Select the spoke’s interface to the internal (private) network.
<b>Local Protected Subnet</b>	Select the spoke address you defined in Step 1.
<b>Outgoing VPN Interface</b>	Select the spoke’s interface to the external (public) network.
<b>Remote Protected Subnet</b>	Select the hub address you defined in Step 2.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the name of the phase 1 configuration you defined.  Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.

## Configuring security policies for spoke-to-spoke communication

Each spoke requires security policies to enable communication with the other spokes. Instead of creating separate security policies for each spoke, you can create an address group that contains the addresses of the networks behind the other spokes. The security policy then applies to all of the spokes in the group.

1. Define destination addresses to represent the networks behind each of the other spokes. Add these addresses to an address group.
2. Define the security policy to enable communication between this spoke and the spokes in the address group you created.

### Policy-based VPN security policy

Define an IPsec security policy to permit communications with the other spokes. See [“Defining VPN security policies” on page 1660](#). Enter these settings in particular:

### Route-based VPN security policy

Define two security policies to permit communications to and from the other spokes.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter these settings in particular:

<b>Incoming Interface</b>	Select the virtual IPsec interface you created.
<b>Source Address</b>	Select the spoke address group you defined in Step 1.
<b>Outgoing Interface</b>	Select the spoke’s interface to the internal (private) network.

---

<b>Destination Address</b>	Select this spoke's address name.
----------------------------	-----------------------------------

---

<b>Action</b>	Select <i>ACCEPT</i> .
---------------	------------------------

---

<b>Enable NAT</b>	Enable
-------------------	--------

---

4. Select *Create New*, leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*, and enter these settings:

---

<b>Incoming Interface</b>	Select the spoke's interface to the internal (private) network.
---------------------------	---

---

<b>Source Address</b>	Select this spoke's address name.
-----------------------	-----------------------------------

---

<b>Outgoing Interface</b>	Select the virtual IPsec interface you created.
---------------------------	---

---

<b>Destination Address</b>	Select the spoke address group you defined in Step 1.
----------------------------	---

---

<b>Action</b>	Select <i>ACCEPT</i> .
---------------	------------------------

---

<b>Enable NAT</b>	Enable
-------------------	--------

---

### Policy-based VPN security policy

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter the following:

---

<b>Local Interface</b>	Select this spoke's internal (private) network interface.
------------------------	---

---

<b>Local Protected Subnet</b>	Select this spoke's source address.
-------------------------------	-------------------------------------

---

<b>Outgoing VPN Interface</b>	Select the spoke's interface to the external (public) network.
-------------------------------	--

---

<b>Remote Protected Subnet</b>	Select the spoke address group you defined in Step 1.
--------------------------------	---

---

<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the name of the phase 1 configuration you defined.  Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.
-------------------	--

---

Place this policy or policies in the policy list above any other policies having similar source and destination addresses.

## Dynamic spokes configuration example

This example demonstrates how to set up a basic route-based hub-and-spoke IPsec VPN that uses preshared keys to authenticate VPN peers.

**Figure 260:**Example hub-and-spoke configuration

In the example configuration, the protected networks 10.1.0.0/24, 10.1.1.0/24 and 10.1.2.0/24 are all part of the larger subnet 10.1.0.0/16. The steps for setting up the example hub-and-spoke configuration create a VPN among Site 1, Site 2, and the HR Network.

The spokes are dialup. Their addresses are not part of the configuration on the hub, so only one spoke definition is required no matter the number of spokes. For simplicity, only two spokes are shown.

### Configure the hub (FortiGate\_1)

The phase 1 configuration defines the parameters that FortiGate\_1 will use to authenticate spokes and establish secure connections.

For the purposes of this example, one preshared key will be used to authenticate all of the spokes. Each key must contain at least 6 printable characters and best practices dictates that it only be known by network administrators. For optimum protection against currently known attacks, each key must consist of a minimum of 16 randomly chosen alphanumeric characters.

## Define the IPsec configuration

### To define the phase 1 parameters

1. At FortiGate\_1, go to *VPN > IPsec > Auto Key (IKE)*.
2. Define the phase 1 parameters that the hub will use to establish a secure connection to the spokes. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Enter a name (for example, toSpokes).
<b>Remote Gateway</b>	Dialup user
<b>Local Interface</b>	External
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID

The basic phase 2 settings associate IPsec phase 2 parameters with the phase 1 configuration and specify the remote end points of the VPN tunnels.

### To define the phase 2 parameters

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 2*, enter the following information, and select *OK*:

<b>Name</b>	Enter a name for the phase 2 definition (for example, toSpokes_ph2).
<b>Phase 1</b>	Select the Phase 1 configuration that you defined previously (for example, toSpokes).

## Define the security policies

security policies control all IP traffic passing between a source address and a destination address. For a route-based VPN, the policies are simpler than for a policy-based VPN. Instead of an IPSEC policy, you use an ACCEPT policy with the virtual IPsec interface as the external interface.

Before you define security policies, you must first define firewall addresses to use in those policies. You need addresses for:

- the HR network behind FortiGate\_1
- the aggregate subnet address for the protected networks

### To define the IP address of the HR network behind FortiGate\_1

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New*, enter the following information, and select *OK*:

<b>Name</b>	Enter an address name (for example, HR_Network).
-------------	--

<b>Type</b>	Subnet
<b>Subnet/IP Range</b>	Enter the IP address of the HR network behind FortiGate_1 (for example, 10.1.0.0/24).

### To specify the IP address the aggregate protected subnet

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New*, enter the following information, and select *OK*:

<b>Address Name</b>	Enter an address name (for example, Spoke_net).
<b>Type</b>	Subnet
<b>Subnet/IP Range</b>	Enter the IP address of the aggregate protected network, 10.1.0.0/16

### To define the security policy for traffic from the hub to the spokes

1. Go to *Policy > Policy > Policy*. and select *Create New*,
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Select the interface to the HR network, <i>port 1</i> .
<b>Source Address</b>	Select <i>HR_Network</i> .
<b>Outgoing Interface</b>	Select the virtual IPsec interface that connects to the spokes, <i>toSpokes</i> .
<b>Destination Address</b>	Select <i>Spoke_net</i> .
<b>Action</b>	Select <i>ACCEPT</i> .

Place the policy in the policy list above any other policies having similar source and destination addresses.

## Configure communication between spokes

Spokes communicate with each other through the hub. You need to configure the hub to allow this communication. An easy way to do this is to create a zone containing the virtual IPsec interfaces even if there is only one, and create a zone-to-zone security policy.

### To create a zone for the VPN

1. Go to *System > Network > Interfaces*.
2. Select the down-arrow on the *Create New* button and select *Zone*.
3. In the *Zone Name* field, enter a name, such as *Our\_VPN\_zone*.
4. Select *Block intra-zone traffic*.  
You could enable intra-zone traffic and then you would not need to create a security policy. But, you would not be able to apply UTM features.
5. In *Interface Members*, select the virtual IPsec interface, *toSpokes*.
6. Select *OK*.

### To create a security policy for the zone

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter these settings:

<b>Incoming Interface</b>	Select <i>Our_VPN_zone</i> .
<b>Source Address</b>	Select <i>All</i> .
<b>Outgoing Interface</b>	Select <i>Our_VPN_zone</i> .
<b>Destination Address</b>	Select <i>All</i> .
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Enable.

4. Select *OK*.

## Configure the spokes

In this example, all spokes have nearly identical configuration, requiring the following:

- phase 1 authentication parameters to initiate a connection with the hub
- phase 2 tunnel creation parameters to establish a VPN tunnel with the hub
- a source address that represents the network behind the spoke. This is the only part of the configuration that is different for each spoke.
- a destination address that represents the aggregate protected network
- a security policy to enable communications between the spoke and the aggregate protected network

### Define the IPsec configuration

At each spoke, create the following configuration.

#### To define the Phase 1 parameters

1. At the spoke, go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Type a name, for example, <i>toHub</i> .
<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Enter <i>172.16.10.1</i> .
<b>Local Interface</b>	Select <i>Port2</i> .
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key. The value must be identical to the preshared key that you specified previously in the <i>FortiGate_1</i> configuration

<b>Peer Options</b>	Select <i>Accept any peer ID</i> .
<b>Enable IPsec Interface Mode</b>	Select <i>Advanced</i> to see this option. Enable the option to create a route-based VPN.

### To define the Phase 2 parameters

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 2*, enter the following information, and select *OK*:

<b>Name</b>	Enter a name for the tunnel, for example, <code>toHub_ph2</code> .
<b>Phase 1</b>	Select the name of the phase 1 configuration that you defined previously, for example, <code>toHub</code> .
<b>Advanced</b>	Select to show the following <i>Quick Mode Selector</i> settings.
<b>Source</b>	Enter the address of the protected network at this spoke. For <code>spoke_1</code> , this is <code>10.1.1.0/24</code> . For <code>spoke_2</code> , this is <code>10.1.2.0/24</code> .
<b>Destination</b>	Enter the aggregate protected subnet address, <code>10.1.0.0/16</code> .

## Define the security policies

You need to define firewall addresses for the spokes and the aggregate protected network and then create a security policy to enable communication between them.

### To define the IP address of the network behind the spoke

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New*, enter the following information, and select *OK*:

<b>Address Name</b>	Enter an address name, for example <code>LocalNet</code> .
<b>Type</b>	Subnet
<b>Subnet/IP Range</b>	Enter the IP address of the private network behind the spoke. For <code>spoke_1</code> , this is <code>10.1.1.0/24</code> . For <code>spoke_2</code> , this is <code>10.1.2.0/24</code> .

### To specify the IP address of the aggregate protected network

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New*, enter the following information, and select *OK*:

<b>Address Name</b>	Enter an address name, for example, <code>Spoke_net</code> .
<b>Type</b>	Subnet
<b>Subnet/IP Range</b>	Enter the IP address of the aggregate protected network, <code>10.1.0.0/16</code> .

### To define the security policy

1. Go to *Policy > Policy > Policy* and select *Create New*.

2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following and select *OK*:

<b>Incoming Interface</b>	Select the virtual IPsec interface, <code>toHub</code> .
<b>Source Address</b>	Select the aggregate protected network address <code>Spoke_net</code> .
<b>Outgoing Interface</b>	Select the interface to the internal (private) network, <code>port1</code> .
<b>Destination Address</b>	Select the address for this spoke's protected network <code>LocalNet</code> .
<b>Action</b>	Select <i>ACCEPT</i> .

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
6. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Select the interface to the internal private network, <code>port1</code> .
<b>Source Address</b>	Select the address for this spoke's protected network, <code>LocalNet</code> .
<b>Outgoing Interface</b>	Select the virtual IPsec interface, <code>toHub</code> .
<b>Destination Address</b>	Select the aggregate protected network address, <code>Spoke_net</code> .
<b>Action</b>	Select <i>ACCEPT</i> .

Place these policies in the policy list above any other policies having similar source and destination addresses.

# Dynamic DNS configuration

This section describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a domain name and a dynamic IP address.

The following topics are included in this section:

- [Dynamic DNS over VPN concepts](#)
- [Dynamic DNS topology](#)
- [General configuration steps](#)
- [Configure the dynamically-addressed VPN peer](#)
- [Configure the fixed-address VPN peer](#)
- [Testing](#)

## Dynamic DNS over VPN concepts

A typical computer has a static IP address and one or more DNS servers to resolve fully qualified domain names (FQDN) into IP addresses. A domain name assigned to this computer is resolved by any DNS server having an entry for the domain name and its static IP address. The IP address never changes or changes only rarely so the DNS server can reliably say it has the correct address for that domain all the time.

### Dynamic DNS (DDNS)

It is different when a computer has a dynamic IP address, such as an IP address assigned dynamically by a DHCP server, and a domain name. Computers that want to contact this computer do not know what its current IP address is. To solve this problem there are dynamic DNS servers. These are public servers that store a DNS entry for your computer that includes its current IP address and associated domain name. These entries are kept up to date by your computer sending its current IP address to the dynamic DNS (DDNS) server to ensure its entry is always up to date. When other computers want to contact your domain, their DNS gets your IP address from your DDNS server. To use DDNS servers, you must subscribe to them and usually pay for their services.

When configuring DDNS on your FortiGate unit, go to *System > Network > DNS* and enable *Enable FortiGuard DDNS*. Then select the interface with the dynamic connection, which DDNS server you have an account with, your domain name, and account information. If your DDNS server is not on the list, there is a generic option where you can provide your DDNS server information.

### Routing

When an interface has some form of changing IP address (DDNS, PPPoE, or DHCP assigned address), routing needs special attention. The standard static route cannot handle the changing IP address. The solution is to use the dynamic-gateway command in the CLI. Say for example you already have four static routes, and you have a PPPoE connection over the wan2 interface and you want to use that as your default route.

The route is configured on the dynamic address VPN peer trying to access the static address FortiGate unit.

## To configure dynamic gateway routing - CLI

```
config router static
  edit 5
    set dst 0.0.0.0 0.0.0.0
    set dynamic-gateway enable
    set device wan2
  next
end
```

[handbook chapter](#)

## Dynamic DNS over VPN

IPsec VPN expects an IP address for each end of the VPN tunnel. All configuration and communication with that tunnel depends on the IP addresses as reference points. However, when the interface the tunnel is on has DDNS enabled there is no set IP address. The remote end of the VPN tunnel now needs another way to reference your end of the VPN tunnel. This is accomplished using Local ID.

A FortiGate unit that has a domain name and a dynamic IP address can initiate VPN connections anytime. The remote peer can reply to the local FortiGate unit using the source IP address that was sent in the packet header because it is current. Without doing a DNS lookup first, the remote peer runs the risk of the dynamic IP changing before it attempts to connect. To avoid this, the remote peer must perform a DNS lookup for the domain name of to be sure of the dynamic IP address before initiating the connection.

### Remote Gateway

When configuring the Phase 1 entry for a VPN tunnel, the Remote Gateway determines the addressing method the remote end of the tunnel uses as one of Static IP Address, Dialup User, or Dynamic DNS. There are different fields for each option.

When you select the Dynamic DNS VPN type there is a related field called Dynamic DNS. The Dynamic DNS field is asking for the FQDN of the remote end of the tunnel. It uses this information to look up the IP address of the remote end of the tunnel through the DDNS server associated with that domain name.

### Local ID (peer ID)

The Local ID or peer ID can be used to uniquely identify one end of a VPN tunnel. This enables a more secure connection. Also if you have multiple VPN tunnels negotiating, this ensures the proper remote and local ends connect. When you configure it on your end, it is your Local ID. When the remote end connects to you, they see it as your peer ID.

If you are debugging a VPN connection, the Local ID is part of the VPN negotiations. You can use it to help troubleshoot connection problems.

## To configure your Local ID

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create New Phase 1* or edit an existing Phase 1 entry.
3. Select *Advanced*.
4. In the *P1 Proposal* section, enter your Local ID.
5. Select *OK*.

The default configuration is to accept all local IDs (peer IDs). If you have the Local ID set, the remote end of the tunnel must be configured to accept your Local ID.

### To accept a specific Peer ID

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create New Phase 1*.
3. Select *Aggressive mode*.
4. For *Peer Options*, select *Accept this peer ID*. This option becomes visible only when Aggressive mode is selected.
5. Enter the string the other end of the tunnel used for its Local ID.
6. Configure the rest of the Phase 1 entry as required.
7. Select *OK*.

### Route-based or policy-based VPN

VPN over dynamic DNS can be configured with either route-based or policy-based VPN settings. Both are valid, but have differences in configuration. Choose the best method based on your requirements. For more information on route-based and policy-based, see [“Types of VPNs” on page 1620](#).

Route-based VPN configuration requires two security policies to be configured (one for each direction of traffic) to permit traffic over the VPN virtual interface, and you must also add a static route entry for that VPN interface or the VPN traffic will not reach its destination. See [“Creating branch\\_2 route-based security policies” on page 1702](#) and [“Creating branch\\_1 route-based security policies” on page 1706](#).

Policy-based VPN configuration uses more complex and often more IPsec security policies, but does not require a static route entry. It has the benefit of being able to configure multiple policies for handling multiple protocols in different ways, such as more scanning of less secure protocols or guaranteeing a minimum bandwidth for protocols such as VoIP. See [“Creating branch\\_2 policy-based security policies” on page 1703](#) and [“Creating branch\\_1 policy-based security policies” on page 1707](#).

## Dynamic DNS topology

In this scenario, two branch offices each have a FortiGate unit and are connected in a gateway-to-gateway VPN configuration. One FortiGate unit has a domain name (example.com) with a dynamic IP address. See [branch\\_2](#) in [Figure 261](#).

Whenever the [branch\\_2](#) unit connects to the Internet (and possibly also at predefined intervals set by the ISP), the ISP may assign a different IP address to the FortiGate unit. The unit has its domain name registered with a dynamic DNS service. The [branch\\_2](#) unit checks in with the DDNS server on a regular basis, and that server provides the DNS information for the domain name, updating the IP address from time to time. Remote peers have to locate the [branch\\_2](#) FortiGate unit through a DNS lookup each time to ensure the address they get is current and correct.

**Figure 261:**Example dynamic DNS configuration

When a remote peer (such as the `branch_1` FortiGate unit in [Figure 261](#)) initiates a connection to `example.com`, the local DNS server looks up and returns the IP address that matches the domain name `example.com`. The remote peer uses the retrieved IP address to establish a VPN connection with the `branch_2` FortiGate unit.

## Assumptions

- You have administrator access to both FortiGate units.
- Both FortiGate units have interfaces named `wan1` and `internal`. (If not, you can use the alias feature to assign these labels as “nicknames” to other interfaces to follow this example.)
- Both FortiGate units have the most recent firmware installed, have been configured for their networks, and are currently passing normal network traffic.
- The `branch_2` FortiGate unit has its `wan1` interface defined as a dynamic DNS interface with the domain name of `example.com`.
- A basic gateway-to-gateway configuration is in place (see [“Gateway-to-gateway configurations” on page 1665](#)) except one of the FortiGate units has a static domain name and a dynamic IP address instead of a static IP address.
- The FortiGate unit with the domain name is subscribed to one of the supported dynamic DNS services. Contact one of the services to set up an account. For more information and instructions about how to configure the FortiGate unit to push its dynamic IP address to a dynamic DNS server, see the [System Administration handbook chapter](#).

## General configuration steps

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec phase 1 parameters to establish a secure connection and authenticate the VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec phase 2 parameters and applies the security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed:

- Configure the branch\_2 FortiGate unit with the dynamic IP address. This unit uses a Local ID string instead of an IP address to identify itself to the remote peer. See [“Configure the dynamically-addressed VPN peer” on page 1699](#).
  - [Configuring branch\\_2 VPN tunnel settings](#)
  - [Configuring branch\\_2 security policies](#)
- Configure the fixed-address VPN peer. To initiate a VPN tunnel with the dynamically-addressed peer, this unit must first retrieve the IP address for the domain from the dynamic DNS service. See [“Configure the fixed-address VPN peer” on page 1704](#).
  - [Configuring branch\\_1 VPN tunnel settings](#)
  - [Configuring branch\\_1 security policies](#)

## Configure the dynamically-addressed VPN peer

It is assumed that this FortiGate unit (branch\_2) has already had its public facing interface, for example the wan1, configured with the proper dynamic DNS configuration.

**Figure 262:**Configure branch\_2, the dynamic address side

Configuring the dynamically-addressed VPN peer includes:

- [Configuring branch\\_2 VPN tunnel settings](#)
- [Configuring branch\\_2 security policies](#)

### Configuring branch\_2 VPN tunnel settings

Define the phase 1 parameters needed to establish a secure connection with the remote peer. See [“Auto Key phase 1 parameters” on page 1637](#). During this procedure you need to choose if you will be using route-based or policy-based VPNs.

#### To configure branch\_2 VPN tunnel settings

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create New Phase 1*.

3. Enter the following information.

<b>Name</b>	Enter <code>branch_2</code> , a name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies, and the VPN monitor.
<b>Remote Gateway</b>	Select <i>Static IP Address</i> .  The remote peer this FortiGate is connecting to has a static IP public address.  If the remote interface is PPPoE do not select <i>Retrieve default gateway from server</i> .
<b>IP Address</b>	Enter <code>172.16.20.1</code> . The IP address of the public interface to the remote peer.
Enter <code>172.16.20.1</code>  The IP address of the public interface to the remote peer.	Select <i>Aggressive</i> .

4. Select *Advanced* and complete the following:

<b>Enable IPsec Interface Mode</b>	Enable for a route-based VPN and when configuring policies, go to <a href="#">“Creating branch_2 route-based security policies” on page 1702</a> .  Disable for a policy-based VPN and when configuring policies, go to <a href="#">“Creating branch_2 policy-based security policies” on page 1703</a> .  If enabled, default settings are used.
<b>Local ID</b>	Enter <code>example.com</code> .  A character string used by the <code>branch_2</code> FortiGate unit to identify itself to the remote peer.  This value must be identical to the value in the <i>Accept this peer ID</i> field of the phase 1 remote gateway configuration on the <code>branch_1</code> remote peer. See <a href="#">“Configuring branch_1 VPN tunnel settings” on page 1704</a> .

5. Select *Create Phase 2*.

Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. For details on phase 2, see [“Phase 2 parameters” on page 1653](#).

6. Enter the following information and select *OK*.

<b>Name</b>	Enter <code>branch_2_phase2</code> .  A name to identify this phase 2 configuration.
<b>Phase 1</b>	Select <code>branch_2</code> .  The name of the phase 1 configuration that you defined earlier.

## Configuring branch\_2 security policies

Define security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [“Defining VPN security policies” on page 1660](#).

After defining the two address ranges, select one of [“Creating branch\\_2 route-based security policies” on page 1702](#) or [“Creating branch\\_2 policy-based security policies” on page 1703](#) to configure the appropriate VPN policies.

### Define address ranges for branch\_2 security policies

Define VPN connection names for the address ranges of the private networks. These addresses are used in the security policies that permit communication between the networks. For more information, see [“Defining policy addresses” on page 1659](#).

Define an address name for the IP address and netmask of the private network behind the local FortiGate unit.

#### To define branch\_2 address ranges

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New*.
3. Enter the following information, and select *OK*.

<b>Name</b>	Enter <code>branch_2_internal</code> . Enter a meaningful name.
<b>Type</b>	Select <i>Subnet</i> .
<b>Subnet / IP Range</b>	Enter <code>10.10.10.0/24</code> . Include the netmask or specify a specific range.
<b>Interface</b>	Select <i>internal</i> . The interface that will be handling the traffic from the internal network.

Define an address name for the IP address and netmask of the private network behind the remote peer.

4. Select *Create New*.
5. Enter the following information, and select *OK*.

<b>Name</b>	Enter <code>branch_1_internal</code> . A meaningful name for the private network at the remote end of the VPN tunnel.
<b>Type</b>	Select <i>Subnet</i> .
<b>Subnet / IP Range</b>	Enter <code>192.168.1.0/24</code> . Include the netmask. Optionally you can specify a range
<b>Interface</b>	Select <i>any</i> .  The interface that will be handling the remote VPN traffic on this FortiGate unit. If you are unsure, or multiple interfaces may be handling this traffic use <i>any</i> .

## Creating branch\_2 route-based security policies

Define ACCEPT security policies to permit communication between the branch\_2 and branch\_1 private networks. Once the route-based policy is configured a routing entry must be configured to route traffic over the VPN interface.

Define a policy to permit the branch\_2 local FortiGate unit to initiate a VPN session with the branch\_1 VPN peer.

### To create route-based security policies

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*.

<b>Incoming Interface</b>	Select <i>internal</i> . The interface that connects to the private network behind this FortiGate unit.
<b>Source Address</b>	Select <i>branch_2_internal</i> . Select the address name for the private network behind this FortiGate unit.
<b>Outgoing Interface</b>	Select <i>branch_2</i> . The VPN Tunnel (IPsec Interface).
<b>Destination Address</b>	Select <i>branch_1_internal</i> . The address name the private network behind the remote peer.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable.
<b>Comments</b>	Route-based: Initiate a branch_2 to branch_1 VPN tunnel.

Define a policy to permit the branch\_1 remote VPN peer to initiate VPN sessions.

1. Select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*.

<b>Incoming Interface</b>	Select <i>branch_2</i> . The VPN Tunnel (IPsec Interface).
<b>Source Address</b>	Select <i>branch_1_internal</i> . The address name for the private network behind the remote peer.
<b>Outgoing Interface</b>	Select <i>internal</i> . The interface connecting the private network behind this FortiGate unit.
<b>Destination Address</b>	Select <i>branch_2_internal</i> . The address name for the private network behind this FortiGate unit.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable.
<b>Comments</b>	Route-based: Initiate a branch_1 to branch_2 internal VPN tunnel.

4. Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.
5. Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

#### To create routing entry for VPN interface - CLI

```
config router static
  edit 5
    set dst 0.0.0.0 0.0.0.0
    set dynamic-gateway enable
    set device wan1
  next
end
```

This routing entry must be added in the CLI because the dynamic-gateway option is not available in the web-based manager.

### Creating branch\_2 policy-based security policies

Define an IPsec policy to permit VPN sessions between the private networks. Define an IPsec policy to permit the VPN sessions between the local branch\_2 unit and the remote branch\_1 unit.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter the following information, and select *OK*.

<b>Local Interface</b>	Select <i>internal</i> . The interface connecting the private network behind this FortiGate unit.
<b>Local Protected Subnet</b>	Select <i>branch_2_internal</i> . The address name for the private network behind this local FortiGate unit.
<b>Outgoing VPN Interface</b>	Select <i>wan1</i> . The FortiGate unit's public interface.
<b>Remote Protected Subnet</b>	Select <i>branch_1_internal</i> . The address name for the private network behind branch_1, the remote peer.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select <i>branch_2</i> from the drop-down list. The name of the phase 1 tunnel.
	Select <i>Allow traffic to be initiated from the remote site</i> .
<b>Comments</b>	Policy-based: allows traffic in either direction to initiate the VPN tunnel.

4. Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.
5. Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

# Configure the fixed-address VPN peer

The fixed-address VPN peer, branch\_1, needs to retrieve the IP address from the dynamic DNS service to initiate communication with the dynamically-addressed peer, branch\_2. It also depends on the peer ID (local ID) to initiate the VPN tunnel with branch\_2.

Figure 263:Configure branch\_1, the fixed address side

Configuring the fixed-address VPN peer includes:

- [Configuring branch\\_1 VPN tunnel settings](#)
- [Configuring branch\\_1 security policies](#)

## Configuring branch\_1 VPN tunnel settings

Define the phase 1 parameters needed to establish a secure connection with the remote peer. For more information, see [“Auto Key phase 1 parameters” on page 1637](#).

### To configure branch\_1 phase 1 VPN settings

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create New Phase 1*.
3. Enter the following information and select *OK*.

<b>Name</b>	Enter <i>branch_1</i> . A name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies and the VPN monitor.
<b>Remote Gateway</b>	Select <i>Dynamic DNS</i> . The remote peer this FortiGate is connecting to has a dynamic IP address.
<b>Dynamic DNS</b>	Type the fully qualified domain name of the remote peer (for example, <i>example.com</i> ).
<b>Interface</b>	Select <i>wan1</i> . The public facing interface on the fixed-address FortiGate unit.
<b>Mode</b>	Select <i>Aggressive</i> .

<b>Peer Options</b>	Select <i>Accept this peer ID</i> , and enter <code>example.com</code> . This option only appears when the mode is set to Aggressive. The identifier of the FortiGate unit with the dynamic address.
<b>Enable IPsec Interface Mode</b>	<p>Enable for a route-based VPN and when configuring policies, go to <a href="#">“Creating branch_1 route-based security policies” on page 1706</a>.</p> <p>Disable for a policy-based VPN and when configuring policies, go to <a href="#">“Creating branch_1 policy-based security policies” on page 1707</a>.</p> <p>If Interface mode is enabled, default settings are used.</p>

4. Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. See [“Phase 2 parameters” on page 1653](#). Enter these settings in particular:

<b>Name</b>	Enter <code>branch_1_p2</code> . A name to identify this phase 2 configuration.
<b>Phase 1</b>	<p>Select <i>branch_1</i>.</p> <p>The name of the phase 1 configuration that you defined for the remote peer. You can select the name of the remote gateway from the Dynamic DNS part of the list.</p>

## Configuring branch\_1 security policies

The `branch_1` FortiGate unit has a fixed IP address and will be connecting to the `branch_2` FortiGate unit that has a dynamic IP address and a domain name of `example.com`. Remember if you are using route-based security policies that you must add a route for the VPN traffic.

### Defining address ranges for branch\_1 security policies

As with `branch_2` previously, `branch_1` needs address ranges defined as well. See [“Defining policy addresses” on page 1659](#).

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New*.
3. Enter the following information, and select *OK*.

<b>Name</b>	Enter <code>branch_2_internal</code> . A meaningful name for the private network behind the <code>branch_2</code> FortiGate unit.
<b>Type</b>	Select <i>Subnet</i> .
<b>Subnet / IP Range</b>	Enter <code>10.10.10.0/24</code> . Include the netmask or specify a specific range.
<b>Interface</b>	Select <i>internal</i> . This is the interface on this FortiGate unit that will be handling with this traffic.

4. Define an address name for the IP address and netmask of the private network behind the remote peer.
5. Select *Create New*.

6. Enter the following information, and select *OK*.

<b>Name</b>	Enter <code>branch_1_internal</code> . A meaningful name for the private network behind the <code>branch_1</code> peer.
<b>Type</b>	Select <i>Subnet</i> .
<b>Subnet / IP Range</b>	Enter <code>192.168.1.0/24</code> . Include the netmask or specify a specific range.
<b>Interface</b>	Select <i>any</i> . The interface on this FortiGate unit that will be handling with this traffic. If you are unsure, or multiple interfaces may be handling this traffic use <i>any</i> .

### Creating `branch_1` route-based security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses. See [“Defining VPN security policies” on page 1660](#).

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*.

<b>Incoming Interface</b>	Select <i>internal</i> . The interface that connects to the private network behind the <code>branch_1</code> FortiGate unit.
<b>Source Address</b>	Select <i>branch_1_internal</i> . The address name that you defined for the private network behind this FortiGate unit.
<b>Outgoing Interface</b>	Select <i>branch_1</i> . The VPN Tunnel (IPsec Interface) you configured earlier.
<b>Destination Address</b>	Select <i>branch_2_internal</i> . The address name that you defined for the private network behind the <code>branch_2</code> peer.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable
<b>Comments</b>	Internal -> branch2

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
6. Enter the following information, and select *OK*.

<b>Incoming Interface</b>	Select <i>branch_1</i> . The VPN Tunnel (IPsec Interface) you configured earlier.
<b>Source Address</b>	Select <i>branch_2_internal</i> . The address name that you defined for the private network behind the <code>branch_2</code> remote peer.
<b>Outgoing Interface</b>	Select <i>internal</i> . The interface that connects to the private network behind this FortiGate unit.

<b>Destination Address</b>	Select <i>branch_1_internal</i> . The address name that you defined for the private network behind this FortiGate unit.
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable
<b>Comments</b>	branch_2 -> Internal

## Creating branch\_1 policy-based security policies

A policy-based security policy allows you the flexibility to allow inbound or outbound traffic or both through this single policy.

This policy-based IPsec VPN security policy allows both inbound and outbound traffic

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter the following information, and select *OK*.

<b>Local Interface</b>	Select <i>internal</i> . The interface that connects to the private network behind this FortiGate unit.
<b>Local Protected Subnet</b>	Select <i>branch_1_internal</i> . The address name that you defined for the private network behind this FortiGate unit.
<b>Outgoing VPN Interface</b>	Select <i>wan1</i> . The FortiGate unit's public interface.
<b>Remote Protected Subnet</b>	Select <i>branch_2_internal</i> . The address name that you defined for the private network behind the remote peer.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select <i>branch_1</i> from the drop-down list.  Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.

4. Place this security policy in the policy list above any other policies having similar source and destination addresses.

## Testing

Once both ends are configured, you can test the VPN tunnel.

### To test the VPN initiated by branch\_2

1. On branch\_2, go to *VPN > Monitor > IPsec Monitor*.  
All IPsec VPN tunnels will be listed on this page, no matter if they are connected or disconnected.
2. Select the tunnel listed for branch\_2, and select the status column for that entry.  
The status will say *Bring Up* and remote port, incoming and outgoing data will all be zero. This indicates an inactive tunnel. When you select *Bring Up*, the FortiGate will try to set up a VPN session over this tunnel. If it is successful, *Bring Up* will change to *Active*, and the arrow icon will change to a green up arrow icon.
3. If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting:

**To test the VPN initiated by branch\_1**

1. On branch\_1, go to *VPN > Monitor > IPsec Monitor*.
2. Select the tunnel listed for branch\_1, and select the status column.  
The difference between branch\_2 and branch\_1 at this point is that the tunnel entry for branch-1 will not have a remote gateway IP address. It will be resolved when the VPN tunnel is started.
3. If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting.

Some troubleshooting ideas include:

- If there was no entry for the tunnel on the monitor page, check the Auto Key (IKE) page to verify the phase 1 and phase 2 entries exist.
- Check the security policy or policies, and ensure there is an outgoing policy as a minimum.
- Check that you entered a local ID in the phase 1 configuration, and that branch\_1 has the same local ID.
- Ensure the local DNS server has an up-to-date DNS entry for exmaple.com.

For more information on VPN troubleshooting and testing, see [“VPN troubleshooting tips” on page 1826](#).

# FortiClient dialup-client configurations

The FortiClient Endpoint Security application is an IPsec VPN client with antivirus, antispy and firewall capabilities. This section explains how to configure dialup VPN connections between a FortiGate unit and one or more FortiClient Endpoint Security applications.

FortiClient users are usually mobile or remote users who need to connect to a private network behind a FortiGate unit. For example, the users might be employees who connect to the office network while traveling or from their homes.

For greatest ease of use, the FortiClient application can download the VPN settings from the FortiGate unit to configure itself automatically. This section covers both automatic and manual configuration.

The following topics are included in this section:

- [Configuration overview](#)
- [FortiClient-to-FortiGate VPN configuration steps](#)
- [Configure the FortiGate unit](#)
- [Configure the FortiClient Endpoint Security application](#)
- [Adding XAuth authentication](#)
- [FortiClient dialup-client configuration example](#)

## Configuration overview

Dialup users typically obtain dynamic IP addresses from an ISP through Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE). Then, the FortiClient Endpoint Security application initiates a connection to a FortiGate dialup server.

By default the FortiClient dialup client has the same IP address as the host PC on which it runs. If the host connects directly to the Internet, this is a public IP address. If the host is behind a NAT device, such as a router, the IP address is a private IP address. The NAT device must be NAT traversal (NAT-T) compatible to pass encrypted packets (see [“NAT traversal” on page 1649](#)). The FortiClient application also can be configured to use a virtual IP address (VIP). For the duration of the connection, the FortiClient application and the FortiGate unit both use the VIP address as the IP address of the FortiClient dialup client.

For a faster and easier method of configuring a FortiGate - to - FortiClient VPN, see [“One button FortiGate - to - FortiClient Phase1 VPN” on page 1711](#).

The FortiClient application sends its encrypted packets to the VPN remote gateway, which is usually the public interface of the FortiGate unit. It also uses this interface to download VPN settings from the FortiGate unit. See [“Automatic configuration of FortiClient dialup clients” on page 1710](#).

**Figure 264:**Example FortiClient dialup-client configuration

## Peer identification

The FortiClient application can establish an IPsec tunnel with a FortiGate unit configured to act as a dialup server. When the FortiGate unit acts as a dialup server, it does not identify the client using the phase 1 remote gateway address. The IPsec tunnel is established if authentication is successful and the IPsec security policy associated with the tunnel permits access. If configured, the FortiGate unit could also require FortiClient registration, that is, the remote user would be required to have FortiClient installed before connection is completed.

There are several different ways to authenticate dialup clients and restrict access to private networks based on client credentials. For more information, see [“Authenticating remote peers and clients” on page 1642](#).

## Automatic configuration of FortiClient dialup clients

The FortiClient application can obtain its VPN settings from the FortiGate VPN server. FortiClient users need to know only the FortiGate VPN server IP address and their user name and password on the FortiGate unit.

The FortiGate unit listens for VPN policy requests from clients on TCP port 8900. When the dialup client connects:

- The client initiates a Secure Sockets Layer (SSL) connection to the FortiGate unit.
- The FortiGate unit requests a user name and password from the FortiClient user. Using these credentials, it authenticates the client and determines which VPN policy applies to the client.
- Provided that authentication is successful, the FortiGate unit downloads a VPN policy to the client over the SSL connection. The information includes IPsec phase 1 and phase 2 settings, and the IP addresses of the private networks that the client is authorized to access.
- The client uses the VPN policy settings to establish an IPsec phase 1 connection and phase 2 tunnel with the FortiGate unit.

## One button FortiGate - to - FortiClient Phase1 VPN

On the FortiOS VPN IKE page there is a method to create a Phase1 portion of a VPN tunnel between the FortiGate and FortiClient. Very little information is required for this configuration. No encryption or authentication method is required. This feature is ideal for setting up quick VPN connections with basic settings.

On the Phase 1 screen (*VPN > IPsec > Phase 1*) is the option *Create a FortiClient VPN*. When selected, the FortiGate unit requires a few basic VPN configuration related questions. Once all the information is added, select *OK*. This will create a new dial-up IPsec-interface mode tunnel. Phase 1 and Phase 2 will be added using the default ike settings.

The following Settings will be used when creating a one-button FortiClient VPN Phase1 object:

- Remote Gateway: Dialup User
- Mode: Aggressive
- Enable IPsec Interface Mode
- Default setting for P1 and P2 Proposal
- XAUTH Enable as Server (Auto)
- IKE mode-config will be enabled
- Peer Option set to "Accept any peer ID"
- Rest of the setting use the current defaults (Default value needs to be the same on FCT side)

Once the completed, you need to create a default Phase2 configuration. This only requires a name for the Phase2 object, and select the FortiClient connection Phase1 name.

### How the FortiGate unit determines which settings to apply

The FortiGate unit follows these steps to determine the configuration information to send to the FortiClient application:

1. Check the virtual domain associated with the connection to determine which VPN policies might apply.
2. Select the VPN policy that matches the dialup client's user group and determine which tunnel (phase 1 configuration) is involved.
3. Check all IPsec security policies that use the specified tunnel to determine which private networks the dialup clients may access.
4. Retrieve the rest of the VPN policy information from the existing IPsec phase 1 and phase 2 parameters in the dialup-client configuration.

### Using virtual IP addresses

When the FortiClient host PC is located behind a NAT device, unintended IP address overlap issues may arise between the private networks at the two ends of the tunnel. For example, the client's host might receive a private IP address from a DHCP server on its network that by co-incidence is the same as a private IP address on the network behind the FortiGate unit. A conflict will occur in the host's routing table and the FortiClient Endpoint Security application will be unable to send traffic through the tunnel. Configuring virtual IP (VIP) addresses for FortiClient applications prevents this problem.

Using VIPs ensures that client IP addresses are in a predictable range. You can then define security policies that allow access only to that source address range. If you do not use VIPs, the security policies must allow all source addresses because you cannot predict the IP address for a remote mobile user.

The FortiClient application must not have the same IP address as any host on the private network behind the FortiGate unit or any other connected FortiClient application. You can

ensure this by reserving a range of IP addresses on the private network for FortiClient users. Or, you can assign FortiClient VIPs from an uncommonly used subnet such as 10.254.254.0/24 or 192.168.254.0/24.

You can reserve a VIP address for a particular client according to its device MAC address and type of connection. The DHCP server then always assigns the reserved VIP address to the client. For more information about this feature, see the “dhcp reserved-address” section in the “system” chapter of the [FortiGate CLI Reference](#).

On the host computer, you can find out the VIP address that the FortiClient Endpoint Security application is using. For example, in Windows command prompt, type `ipconfig /all`

On Linux or Mac OS X, type `ifconfig` in a terminal window. The output will also show the IP address that has been assigned to the host Network Interface Card (NIC).

---

It is best to assign VIPs using DHCP over IPsec. The FortiGate dialup server can act as a DHCP server or relay requests to an external DHCP server. You can also configure VIPs manually on FortiClient applications, but it is more difficult to ensure that all clients use unique addresses.

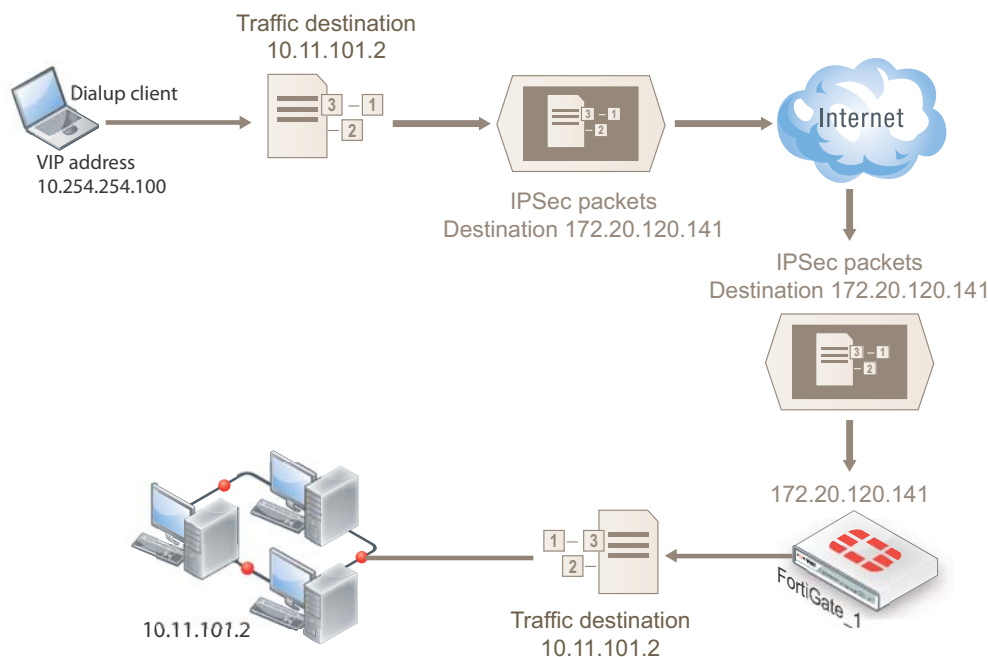

If you assign a VIP on the private network behind the FortiGate unit and enable DHCP-IPsec (a phase 2 advanced option), the FortiGate unit acts as a proxy on the local private network for the FortiClient dialup client. Whenever a host on the network behind the dialup server issues an ARP request for the device MAC address of the FortiClient host, the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel. For more information, see [“DHCP-IPsec” on page 1654](#)

---

FortiGate units fully support [RFC 3456](#). The FortiGate DHCP over IPsec feature can be enabled to allocate VIP addresses to FortiClient dialup clients using a FortiGate DHCP server.

[Figure 265](#) shows an example of a FortiClient-to-FortiGate VPN where the FortiClient application is assigned a VIP on an uncommonly used subnet. The diagram also shows that while the destination for the information in the encrypted packets is the private network behind the FortiGate unit, the destination of the IPsec packets themselves is the public interface of the FortiGate unit that acts as the end of the VPN tunnel.

**Figure 265:** IP address assignments in a FortiClient dialup-client configuration

### Assigning VIPs by RADIUS user group

If you use XAuth authentication, you can assign users the virtual IP address stored in the Framed-IP-Address field of their record on the RADIUS server. (See [RFC 2865](#) and [RFC 2866](#) for more information about RADIUS fields.) To do this:

- Set the DHCP server *IP Assignment Mode* to *User-group defined method*. This is an Advanced setting. See [“To configure a DHCP server on a FortiGate interface” on page 1717](#).
- Create a new firewall user group and add the RADIUS server to it.
- In your phase 1 settings, configure the FortiGate unit as an XAuth server and select from *User Group* the new user group that you created. For more information, see [“Using the FortiGate unit as an XAuth server” on page 1651](#).
- Configure the FortiClient application to use XAuth. See [“Adding XAuth authentication” on page 1718](#).

### FortiClient dialup-client infrastructure requirements

- To support policy-based VPNs, the FortiGate dialup server may operate in either NAT mode or transparent mode. NAT mode is required if you want to create a route-based VPN.
- If the FortiClient dialup clients will be configured to obtain VIP addresses through FortiGate DHCP relay, a DHCP server must be available on the network behind the FortiGate unit and the DHCP server must have a direct route to the FortiGate unit.
- If the FortiGate interface to the private network is not the default gateway, the private network behind the FortiGate unit must be configured to route IP traffic destined for dialup clients back (through an appropriate gateway) to the FortiGate interface to the private network. As an alternative, you can configure the IPsec security policy on the FortiGate unit to perform inbound NAT on IP packets. Inbound NAT translates the source addresses of inbound decrypted packets into the IP address of the FortiGate interface to the local private network.

## FortiClient-to-FortiGate VPN configuration steps

Configuring dialup client capability for FortiClient dialup clients involves the following general configuration steps:

1. If you will be using VIP addresses to identify dialup clients, determine which VIP addresses to use. As a precaution, consider using VIP addresses that are not commonly used.
2. Configure the FortiGate unit to act as a dialup server. See [“Configure the FortiGate unit” on page 1714](#).
3. If the dialup clients will be configured to obtain VIP addresses through DHCP over IPsec, configure the FortiGate unit to act as a DHCP server or to relay DHCP requests to an external DHCP server.
4. Configure the dialup clients. See [“Configure the FortiClient Endpoint Security application” on page 1718](#).

When a FortiGate unit has been configured to accept connections from FortiClient dialup-clients, you can optionally arrange to have an IPsec VPN configuration downloaded to FortiClient dialup clients automatically. For more information, see [“Configuring the FortiGate unit as a VPN policy server” on page 1717](#).

## Configure the FortiGate unit

Configuring the FortiGate unit to establish VPN connections with FortiClient Endpoint Security users involves the following steps:

- Configure the VPN settings
- If the dialup clients use automatic configuration, configure the FortiGate unit as a VPN policy server
- If the dialup clients obtain VIP addresses by DHCP over IPsec, configure an IPsec DHCP server or relay

The procedures in this section cover basic setup of policy-based and route-based VPNs compatible with FortiClient Endpoint Security. A route-based VPN is simpler to configure.

### Configuring FortiGate unit VPN settings

To configure FortiGate unit VPN settings to support FortiClient users, you need to:

- configure the FortiGate Phase 1 VPN settings
  - configure the FortiGate Phase 2 VPN settings
  - add the security policy
1. On the local FortiGate unit, define the phase 1 configuration needed to establish a secure connection with the FortiClient peer. See [“Auto Key phase 1 parameters” on page 1637](#). Enter these settings in particular:

<b>Name</b>	Enter a name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies and the VPN monitor.
<b>Remote Gateway</b>	Select <i>Dialup User</i> .
<b>Local Interface</b>	Select the interface through which clients connect to the FortiGate unit.

<b>Mode</b>	Select <i>Main (ID Protection)</i> .
<b>Authentication Method</b>	Select <i>Pre-shared Key</i> .
<b>Pre-shared Key</b>	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
<b>Peer option</b>	Select <i>Accept any peer ID</i> .
<b>Enable IPsec Interface Mode</b>	You must select <i>Advanced</i> to see this setting. If <i>IPsec Interface Mode</i> is enabled, the FortiGate unit creates a virtual IPsec interface for a route-based VPN.

2. Define the phase 2 parameters needed to create a VPN tunnel with the FortiClient peer. See [“Phase 2 parameters” on page 1653](#). Enter these settings in particular:

<b>Name</b>	Enter a name to identify this phase 2 configuration.
<b>Phase 1</b>	Select the name of the phase 1 configuration that you defined.
<b>Advanced</b>	Select to configure the following optional setting.
<b>DHCP-IPsec</b>	Select if you provide virtual IP addresses to clients using DHCP.

3. Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks. For more information, see [“Defining policy addresses” on page 1659](#).

Enter these settings in particular:

- Define an address name for the individual address or the subnet address that the dialup users access through the VPN.
  - If FortiClient users are assigned VIP addresses, define an address name for the subnet to which these VIPs belong.
4. Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [“Defining VPN security policies” on page 1660](#).

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won't be able to retrieve a lease from the FortiGate's (IPSec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

### Route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter these settings in particular:

<b>Incoming Interface</b>	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
<b>Source Address</b>	Select <i>All</i> .

<b>Outgoing Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Destination Address</b>	Select <i>All</i> .
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable.

If you want to allow hosts on the private network to initiate communications with the FortiClient users after the tunnel is established, you need to define a security policy for communication in that direction.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter these settings in particular:

<b>Incoming Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Source Address</b>	Select <i>All</i> .
<b>Outgoing Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Destination Address</b>	Select <i>All</i> .
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable.

### Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* of *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter these settings in particular:

<b>Local Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Local Protected Subnet</b>	Select the address name that you defined in Step 3 for the private network behind this FortiGate unit.
<b>Outgoing VPN Interface</b>	Select the FortiGate unit's public interface.
<b>Remote Protected Subnet</b>	If FortiClient users are assigned VIPs, select the address name that you defined in Step 3 for the VIP subnet. Otherwise, select <i>All</i> .
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the name of the phase 1 configuration that you created in Step 1.  Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

## Configuring the FortiGate unit as a VPN policy server

When a FortiClient application set to automatic configuration connects to the FortiGate unit, the FortiGate unit requests a user name and password. If the user supplies valid credentials, the FortiGate unit downloads the VPN settings to the FortiClient application.

You must do the following to configure the FortiGate unit to work as a VPN policy server for FortiClient automatic configuration:

1. Create user accounts for FortiClient users.
2. Create a user group for FortiClient users and the user accounts that you created in step 1.
3. Connect to the FortiGate unit CLI and configure VPN policy distribution as follows:

```
config vpn ipsec forticlient
  edit <policy_name>
    set phase2name <tunnel_name>
    set usergroupname <group_name>
    set status enable
  end
```

<tunnel\_name> must be the Name you specified in the step 2 of [“Configure the FortiGate unit” on page 1714](#). <group\_name> must be the name of the user group your created for FortiClient users.

## Configuring DHCP services on a FortiGate interface

If the FortiClient dialup clients are configured to obtain a VIP address using DHCP, configure the FortiGate dialup server to either:

- relay DHCP requests to a DHCP server behind the FortiGate unit (see [“To configure DHCP relay on a FortiGate interface”](#) below).
- act as a DHCP server (see [“To configure a DHCP server on a FortiGate interface” on page 1717](#)).

Note that DHCP services are typically configured during the interface creation stage, but you can return to an interface to modify DHCP settings if need be.

### To configure DHCP relay on a FortiGate interface

1. Go to *System > Network > Interfaces* and select the interface that you want to relay DHCP.
2. Under *DHCP Server*, select *Enable* and create a new *DHCP Address Range* and *Netmask*.
3. Open the *Advanced...* menu and select *Relay* for the *Mode* option.
4. For the *Type*, select *IPsec*.
5. Select *OK*.

### To configure a DHCP server on a FortiGate interface

1. Go to *System > Network > Interfaces* and select the interface that you want to act as a DHCP server.
2. Under *DHCP Server*, select *Enable* and create a new *DHCP Address Range* and *Netmask*.
3. For *Default Gateway*, enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
4. For *DNS Server*, select *Same as System DNS*. If you want to use a different DNS server for VPN clients, select *Specify* and enter an IP address in the available field.

5. Open the *Advanced...* menu and select *Server* for the *Mode* option.
6. For the *Type*, select *IPsec*.
7. Select *OK*.

## Configure the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to communicate with a remote FortiGate dialup server using the VIP address that you specify manually. These procedures are based on FortiClient 5.0.

### Configuring FortiClient

This procedure explains how to configure the FortiClient application manually using the default IKE and IPsec settings. For more information, refer to the [FortiClient Administration Guide](#).

This procedure includes instructions for configuring a virtual IP for the FortiClient application, either manually or using DHCP over IPsec.

#### To create a FortiClient VPN configuration

1. Go to *Remote Access* and select the down-arrow for the VPN connection.
2. Select *Add new connection* and complete following information:

<b>VPN Type</b>	Select <i>IPsec VPN</i> .
<b>Connection Name</b>	Enter a descriptive name for the connection.
<b>Remote Gateway</b>	Enter the IP address or the fully qualified domain name (FQDN) of the remote gateway.
<b>Authentication Method</b>	Select <i>Pre-shared Key</i> .
<b>Pre-shared Key</b>	Enter the pre-shared key.
<b>User Name</b>	Enter the user name to connect to the tunnel.

3. Select *OK*.

## Adding XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication in a separate exchange at the end of the VPN phase 1 negotiation. The FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.

Implementation of XAuth requires configuration at both the FortiGate unit and the FortiClient application. For information about configuring a FortiGate unit as an XAuth server, see [“Using the FortiGate unit as an XAuth server” on page 1651](#). The following procedure explains how to configure the FortiClient application.

Note that XAuth is not compatible with IKE version 2.

For more information on configuring XAuth authentication, see the [FortiClient Administration Guide](#).

## FortiClient dialup-client configuration example

This example demonstrates how to set up a FortiClient dialup-client IPsec VPN that uses preshared keys for authentication purposes. In the example configuration, the DHCP over IPsec feature is enabled in the FortiClient Endpoint Security application so that the FortiClient Endpoint Security application can acquire a VIP address through the FortiGate DHCP server. Both route-based and policy-based solutions are covered.

**Figure 266:**Example FortiClient dialup-client configuration

In the example configuration:

- VIP addresses that are not commonly used (in this case, 10.254.254.0/24) are assigned to the FortiClient dialup clients using a DHCP server.
- The dialup clients have access to the LAN behind FortiGate\_1.
- The other network devices are assigned IP addresses as shown in [Figure 266](#).

### Configuring FortiGate\_1

When a FortiGate unit receives a connection request from a dialup client, it uses IPsec phase 1 parameters to establish a secure connection and authenticate the client. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec phase 2 parameters and applies the IPsec security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed at the FortiGate unit:

- Define the phase 1 parameters that the FortiGate unit needs to authenticate the dialup clients and establish a secure connection. See [“To define the phase 1 parameters” on page 1720](#).
- Define the phase 2 parameters that the FortiGate unit needs to create a VPN tunnel and enable all dialup clients having VIP addresses on the 10.254.254.0/24 network to connect using the same tunnel definition. See [“To define the phase 2 parameters” on page 1720](#).
- Create security policy to control the permitted services and permitted direction of traffic between the IP source address and the dialup clients. See [“To define the firewall addresses” on page 1721](#).
- Configure the FortiGate unit to service DHCP requests from dialup clients. See [“Configuring the FortiClient Endpoint Security application” on page 1722](#).

### To define the phase 1 parameters

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	todialups
<b>Remote Gateway</b>	Dialup User
<b>Local Interface</b>	Port 1
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	hardtoguess
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	Select
<b>Enable IPsec Interface Mode</b>	Enable for route-based VPN. Disable for policy-based VPN.

### To define the phase 2 parameters

1. Go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 2*.
2. Select *Advanced*, enter the following information, and select *OK*:

<b>Name</b>	td_2
<b>Phase 1</b>	todialups
<b>Advanced</b>	DHCP-IPsec

### To define the firewall addresses

1. Go to *Firewall Objects > Address > Addresses*.
2. Select *Create New*, enter the following information, and select *OK*:

<b>Name</b>	internal_net
<b>Type</b>	Subnet
<b>Subnet/IP Range</b>	10.11.101.0/24
<b>Interface</b>	Port 2

3. Select *Create New*, enter the following information, and select *OK*:

<b>Name</b>	dialups
<b>Type</b>	IP Range
<b>Subnet/IP Range</b>	10.254.254.1-10.254.254.10
<b>Interface</b>	Route-based VPN: todialups Policy-based VPN: Any

The security policies for route-based and policy-based VPNs are described in separate sections below.

### To define security policies - route-based VPN

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	todialups
<b>Source Address</b>	dialups
<b>Outgoing Interface</b>	Port 2
<b>Destination Address</b>	internal_net
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Disable

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
6. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Port 2
<b>Source Address</b>	internal_net
<b>Outgoing Interface</b>	todialups
<b>Destination Address</b>	dialups

<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Disable

7. Select *Create New*.
8. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
9. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Port 2
<b>Source Address</b>	internal_net
<b>Outgoing Interface</b>	todialups
<b>Destination Address</b>	all
<b>Service</b>	DHCP
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Disable

10. Place these policies in the policy list above any other policies having similar source and destination addresses.

The policy in step 7 is required for DHCP to function properly for policy-based VPNs. You can omit this policy if you change the *Destination Address Name* to *all* in the step before. Route-based policies are not affected by this.

#### To define the security policy - policy-based VPN

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* of *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter the following information, and select *OK*:

<b>Local Interface</b>	Port 2
<b>Local Protected Subnet</b>	internal_net
<b>Outgoing VPN Interface</b>	Port 1
<b>Remote Protected Subnet</b>	dialups
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select <i>todialups</i> from the drop-down list.
<b>Allow traffic to be initiated from the remote site</b>	Enable

4. Place the policy in the policy list above any other policies having similar source and destination addresses.

## Configuring the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to connect to FortiGate\_1 and broadcast a DHCP request. The dialup client uses the VIP

address acquired through FortiGate DHCP relay as its IP source address for the duration of the connection.

**To configure FortiClient**

1. Go to *Remote Access* and select the down-arrow for the VPN connection.
2. Select *Add new connection* and complete following information:

<b>VPN Type</b>	Select <i>IPsec VPN</i> .
<b>Connection Name</b>	Headquarters.
<b>Remote Gateway</b>	The port1 IP address.
<b>Authentication Method</b>	Select <i>Pre-shared Key</i> .
<b>Pre-shared Key</b>	hardtoguess
<b>User Name</b>	Enter the user name to connect to the tunnel.

3. Select *OK*.

# FortiGate dialup-client configurations

This section explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit having a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

The following topics are included in this section:

- [Configuration overview](#)
- [FortiGate dialup-client configuration steps](#)
- [Configure the server to accept FortiGate dialup-client connections](#)
- [Configure the FortiGate dialup client](#)

## Configuration overview

A dialup client can be a FortiGate unit. The FortiGate dialup client typically obtains a dynamic IP address from an ISP through the Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE) before initiating a connection to a FortiGate dialup server.

**Figure 267:**Example FortiGate dialup-client configuration

In a dialup-client configuration, the FortiGate dialup server does not rely on a phase 1 remote gateway address to establish an IPsec VPN connection with dialup clients. As long as authentication is successful and the IPsec security policy associated with the tunnel permits access, the tunnel is established.

Several different ways to authenticate dialup clients and restrict access to private networks based on client credentials are available. To authenticate FortiGate dialup clients and help to distinguish them from FortiClient dialup clients when multiple clients will be connecting to the VPN through the same tunnel, best practices dictate that you assign a unique identifier (local ID

or peer ID) to each FortiGate dialup client. For more information, see [“Authenticating remote peers and clients” on page 1642](#).

Whenever you add a unique identifier (local ID) to a FortiGate dialup client for identification purposes, you must select Aggressive mode on the FortiGate dialup server and also specify the identifier as a peer ID on the FortiGate dialup server. For more information, see [“Enabling VPN access with user accounts and pre-shared keys” on page 1645](#).

Users behind the FortiGate dialup server cannot initiate the tunnel because the FortiGate dialup client does not have a static IP address. After the tunnel is initiated by users behind the FortiGate dialup client, traffic from the private network behind the FortiGate dialup server can be sent to the private network behind the FortiGate dialup client.

Encrypted packets from the FortiGate dialup client are addressed to the public interface of the dialup server. Encrypted packets from the dialup server are addressed either to the public IP address of the FortiGate dialup client (if the dialup client connects to the Internet directly), or if the FortiGate dialup client is behind a NAT device, encrypted packets from the dialup server are addressed to the public IP address of the NAT device.

If a router with NAT capabilities is in front of the FortiGate dialup client, the router must be NAT-T compatible for encrypted traffic to pass through the NAT device. For more information, see [“NAT traversal” on page 1649](#).

When the FortiGate dialup server decrypts a packet from the FortiGate dialup client, the source address in the IP header may be one of the following values, depending on the configuration of the network at the far end of the tunnel:

- If the FortiGate dialup client connects to the Internet directly, the source address will be the private IP address of a host or server on the network behind the FortiGate dialup client.
- If the FortiGate dialup client is behind a NAT device, the source address will be the public IP address of the NAT device.

In some cases, computers on the private network behind the FortiGate dialup client may (by co-incidence) have IP addresses that are already used by computers on the network behind the FortiGate dialup server. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent.

In many cases, computers on the private network behind the FortiGate dialup client will most likely obtain IP addresses from a local DHCP server behind the FortiGate dialup client. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and IP-address overlap issues may arise.

To avoid these issues, you can configure FortiGate DHCP relay on the dialup client instead of using a DHCP server on the network behind the dialup client. The FortiGate dialup client can be configured to relay DHCP requests from the local private network to a DHCP server that resides on the network behind the FortiGate dialup server (see [Figure 268 on page 1726](#)). You configure the FortiGate dialup client to pass traffic from the local private network to the remote network by enabling FortiGate DHCP relay on the FortiGate dialup client interface that is connected to the local private network.

Afterward, when a computer on the network behind the dialup client broadcasts a DHCP request, the dialup client relays the message through the tunnel to the remote DHCP server. The remote DHCP server responds with a private IP address for the computer. To avoid ambiguous routing and network overlap issues, the IP addresses assigned to computers behind the dialup client cannot match the network address space used by the private network behind the FortiGate dialup server.

**Figure 268:** Preventing network overlap in a FortiGate dialup-client configuration

When the DHCP server resides on the private network behind the FortiGate dialup server, the IP destination address specified in the IPsec security policy on the FortiGate dialup client must refer to that network.

You must add a static route to the DHCP server FortiGate unit if it is not directly connected to the private network behind the FortiGate dialup server; its IP address does not match the IP address of the private network. Also, the destination address in the IPsec security policy on the FortiGate dialup client must refer to the DHCP server address. The DHCP server must be configured to assign a range of IP addresses different from the DHCP server's local network, and also different from the private network addresses behind the FortiGate dialup server. See [“Routing” on page 1695](#).

## FortiGate dialup-client infrastructure requirements

The requirements are:

- The FortiGate dialup server must have a static public IP address.
- NAT mode is required if you want to create a route-based VPN.
- The FortiGate dialup server may operate in either NAT mode or transparent mode to support a policy-based VPN.
- Computers on the private network behind the FortiGate dialup client can obtain IP addresses either from a DHCP server behind the FortiGate dialup client, or a DHCP server behind the FortiGate dialup server.
  - If the DHCP server resides on the network behind the dialup client, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup server.
  - If the DHCP server resides on the network behind the FortiGate dialup server, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup client.

# FortiGate dialup-client configuration steps

The procedures in this section assume that computers on the private network behind the FortiGate dialup client obtain IP addresses from a local DHCP server. The assigned IP addresses do not match the private network behind the FortiGate dialup server.

In situations where IP-address overlap between the local and remote private networks is likely to occur, FortiGate DHCP relay can be configured on the FortiGate dialup client to relay DHCP requests to a DHCP server behind the FortiGate dialup server. For more information, see [“To configure DHCP relay on a FortiGate interface” on page 1717](#).

Configuring dialup client capability for FortiGate dialup clients involves the following general configuration steps:

- Determine which IP addresses to assign to the private network behind the FortiGate dialup client, and add the IP addresses to the DHCP server behind the FortiGate dialup client. Refer to the software supplier’s documentation to configure the DHCP server.
- Configure the FortiGate dialup server. See [“Configure the server to accept FortiGate dialup-client connections” on page 1727](#).
- Configure the FortiGate dialup client. See [“Configure the FortiGate dialup client” on page 1729](#).

## Configure the server to accept FortiGate dialup-client connections

Before you begin, optionally reserve a unique identifier (peer ID) for the FortiGate dialup client. The dialup client will supply this value to the FortiGate dialup server for authentication purposes during the IPsec phase 1 exchange. In addition, the value will enable you to distinguish FortiGate dialup-client connections from FortiClient dialup-client connections. The same value must be specified on the dialup server and on the dialup client.

1. At the FortiGate dialup server, define the phase 1 parameters needed to authenticate the FortiGate dialup client and establish a secure connection. See [“Auto Key phase 1 parameters” on page 1637](#). Enter these settings in particular:

<b>Name</b>	Enter a name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies and the VPN monitor.
<b>Remote Gateway</b>	Select <i>Dialup User</i> .
<b>Local Interface</b>	Select the interface through which clients connect to the FortiGate unit.
<b>Mode</b>	If you will be assigning an ID to the FortiGate dialup client, select <i>Aggressive</i> .

<b>Peer Options</b>	If you will be assigning an ID to the FortiGate dialup client, select <i>Accept this peer ID</i> and type the identifier that you reserved for the FortiGate dialup client into the adjacent field.
<b>Enable IPsec Interface Mode</b>	<p>You must select <i>Advanced</i> to see this setting. If <i>IPsec Interface Mode</i> is enabled, the FortiGate unit creates a virtual IPsec interface for a route-based VPN. Disable this option if you want to create a policy-based VPN.</p> <p>After you select <i>OK</i> to create the phase 1 configuration, you cannot change this setting.</p>

2. Define the phase 2 parameters needed to create a VPN tunnel with the FortiGate dialup client. See [“Phase 2 parameters” on page 1653](#). Enter these settings in particular:

<b>Name</b>	Enter a name to identify this phase 2 configuration.
<b>Phase 1</b>	Select the name of the phase 1 configuration that you defined.

3. Define names for the addresses or address ranges of the private networks that the VPN links. See [“Defining policy addresses” on page 1659](#). Enter these settings in particular:
  - Define an address name for the server, host, or network behind the FortiGate dialup server.
  - Define an address name for the private network behind the FortiGate dialup client.
4. Define the security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [“Defining VPN security policies” on page 1660](#).

### Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind the FortiGate dialup client and the private network behind this FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter these settings in particular:

<b>Incoming Interface</b>	Select the VPN tunnel (IPsec interface) created in Step 1.
<b>Source Address</b>	Select <i>All</i> .
<b>Outgoing Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Destination Address</b>	Select <i>All</i> .
<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable

## Policy-based VPN security policy

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* of *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter these settings in particular:

<b>Local Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Local Protected Subnet</b>	Select the address name that you defined in Step 3 for the private network behind this FortiGate unit.
<b>Outgoing VPN Interface</b>	Select the FortiGate unit's public interface.
<b>Remote Protected Subnet</b>	Select the address name that you defined in Step 3.
<b>VPN Tunnel</b>	<p>Select <i>Use Existing</i> and select the name of the phase 1 configuration that you created in Step 1. from the drop-down list.</p> <p>Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.</p> <p>Clear <i>Allow outbound</i> to prevent traffic from the local network from initiating the tunnel after the tunnel has been established.</p>

4. To prevent traffic from the local network from initiating the tunnel after the tunnel has been established, you need to disable the outbound VPN traffic in the CLI

```
config firewall policy
  edit <policy_number>
    set outbound disable
  end
```

Place the policy in the policy list above any other policies having similar source and destination addresses.

If configuring a route-based policy, configure a default route for VPN traffic on this interface.

## Configure the FortiGate dialup client

Configure the FortiGate dialup client.

1. At the FortiGate dialup client, define the phase 1 parameters needed to authenticate the dialup server and establish a secure connection. See [“Auto Key phase 1 parameters” on page 1637](#). Enter these settings in particular:

<b>Name</b>	Enter a name to identify the VPN tunnel.
<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Type the IP address of the dialup server's public interface.
<b>Local Interface</b>	Select the interface that connects to the public network.

<b>Mode</b>	The FortiGate dialup client has a dynamic IP address, select <i>Aggressive</i> .
<b>Advanced</b>	Select to view the following options.
<b>Local ID</b>	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.
<b>Enable IPsec Interface Mode</b>	<p>If <i>IPsec Interface Mode</i> is enabled, the FortiGate unit creates a virtual IPsec interface for a route-based VPN. Disable this option if you want to create a policy-based VPN.</p> <p>After you select <i>OK</i> to create the phase 1 configuration, you cannot change this setting.</p>

2. Define the phase 2 parameters needed to create a VPN tunnel with the dialup server. See [“Phase 2 parameters” on page 1653](#). Enter these settings in particular:

<b>Name</b>	Enter a name to identify this phase 2 configuration.
<b>Phase 1</b>	Select the name of the phase 1 configuration that you defined.

3. Define names for the addresses or address ranges of the private networks that the VPN links. See [“Defining policy addresses” on page 1659](#). Enter these settings in particular:
  - Define an address name for the server, host, or network behind the FortiGate dialup server.
  - Define an address name for the private network behind the FortiGate dialup client.
4. Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see [“Defining VPN security policies” on page 1660](#).

### Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind this FortiGate dialup client and the private network behind the FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* of *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter these settings in particular:

<b>Incoming Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Source Address</b>	Select <i>All</i> .
<b>Outgoing Interface</b>	Select the VPN tunnel (IPsec interface) created in Step 1.
<b>Destination Address</b>	Select <i>All</i> .

<b>Action</b>	Select <i>ACCEPT</i> .
<b>Enable NAT</b>	Disable

### Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* of *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter these settings in particular:

<b>Local Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Local Protected Subnet</b>	Select the address name that you defined in Step 3 for the private network behind this FortiGate unit.
<b>Outgoing Interface</b>	Select the FortiGate unit's public interface.
<b>Remote Protected Subnet</b>	Select the address name that you defined in Step 3 for the private network behind the dialup server.
<b>VPN Tunnel</b>	<p>Select <i>Use Existing</i> and select the name of the phase 1 configuration that you created in Step 1 from the drop-down list.</p> <p>Clear <i>Allow traffic to be initiated from the remote site</i> to prevent traffic from the remote network from initiating the tunnel after the tunnel has been established.</p>

Place the policy in the policy list above any other policies having similar source and destination addresses.

# Supporting IKE Mode config clients

IKE Mode Config is an alternative to DHCP over IPsec. A FortiGate unit can be configured as either an IKE Mode Config server or client. This chapter contains the following sections:

- [Automatic configuration overview](#)
- [IKE Mode Config overview](#)
- [Configuring IKE Mode Config](#)
- [Example: FortiGate unit as IKE Mode Config server](#)
- [Example: FortiGate unit as IKE Mode Config client](#)

## Automatic configuration overview

VPN configuration for remote clients is simpler if it is automated. Several protocols support automatic configuration:

- The Fortinet FortiClient Endpoint Security application can completely configure a VPN connection with a suitably configured FortiGate unit given only the FortiGate unit's address. This protocol is exclusive to Fortinet. For more information, see the [“FortiClient dialup-client configurations”](#) chapter.
- DHCP over IPsec can assign an IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms.
- IKE Mode Config can configure host IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms. Several network equipment vendors support IKE Mode Config, which is described in the ISAKMP Configuration Method document [draft-dukes-ike-mode-cfg-02.txt](#).

This chapter describes how to configure a FortiGate unit as either an IKE Mode Config server or client.

## IKE Mode Config overview

Dialup VPN clients connect to a FortiGate unit that acts as a VPN server, providing the client the necessary configuration information to establish a VPN tunnel. The configuration information typically includes a virtual IP address, netmask, and DNS server address.

IKE Mode Config is available only for VPNs that are route-based, also known as interface-based. A FortiGate unit can function as either an IKE Configuration Method server or client. IKE Mode Config is configurable only in the CLI.

## Configuring IKE Mode Config

IKE Mode Config is configured with the CLI command `config vpn ipsec phase1-interface`. The `mode-cfg` variable enables IKE Mode Config. The `type` field determines whether you are creating an IKE Mode Config server or a client. Setting `type` to `dynamic` creates a server configuration, otherwise the configuration is a client.

## Configuring an IKE Mode Config client

If the FortiGate unit will connect as a dialup client to a remote gateway that supports IKE Mode Config, the relevant `vpn ipsec phase1-interface` variables are as follows:

Variable	Description
<code>ike-version 1</code>	IKE v1 is the default for FortiGate IPsec VPNs.  IKE Mode Config is also compatible with IKE v2 (RFC 4306).
<code>mode-cfg enable</code>	Enable IKE Mode Config.
<code>type {ddns   static}</code>	If you set <code>type</code> to <code>dynamic</code> , an IKE Mode Config server is created.
<code>assign-ip {enable   disable}</code>	Enable to request an IP address from the server.
<code>interface &lt;interface_name&gt;</code>	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
<code>proposal &lt;encryption_combination&gt;</code>	This is a regular IPsec VPN field that determines the encryption and authentication settings that the client will accept. For more information, see <a href="#">“Defining IKE negotiation parameters” on page 1646</a> .
<code>mode-cfg-ip-version {4 6}</code>	Select if the Method client receives an IPv4 or IPv6 IP address. The default is 4. the <code>ip-version</code> setting matches this variable's value.
<code>ip-version &lt;4   6&gt;</code>	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set <code>ip-version</code> to 6 to create a VPN with IPv6 addressing.

For a complete list of available variables, see the [CLI Reference](#).

## Configuring an IKE Mode Config server

If the FortiGate unit will accept connection requests from dialup clients that support IKE Mode Config, the following `vpn ipsec phase1-interface` settings are required before any other configuration is attempted:

Variable	Description
<code>ike-version 1</code>	IKE v1 is the default for FortiGate IPsec VPNs.  IKE Mode Config is also compatible with IKE v2 (RFC 4306).
<code>mode-cfg enable</code>	Enable IKE Mode Config.
<code>type dynamic</code>	Any other setting creates an IKE Mode Config client.
<code>interface &lt;interface_name&gt;</code>	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.

Variable	Description
proposal <encryption_combination>	This is a regular IPsec VPN field that determines the encryption and authentication settings that the server will accept. For more information, see <a href="#">“Defining IKE negotiation parameters” on page 1646</a> .
ip-version <4   6>	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set <code>ip-version</code> to 6 to create a VPN with IPv6 addressing.

For a complete list of available variables, see the [CLI Reference](#).

After you have enabled the basic configuration, you can configure:

- IP address assignment for clients
- DNS and WINS server assignment

## IP address assignment

Usually you will want to assign IP addresses to clients. The simplest method is to assign addresses from a specific range, similar to a DHCP server.

If your clients are authenticated by a RADIUS server, you can obtain the user’s IP address assignment from the Framed-IP-Address attribute. The user must be authenticated using XAuth.

### To assign IP addresses from an address range

If your VPN uses IPv4 addresses,

```
config vpn ipsec phase1-interface
edit vpn1
    set mode-cfg-ipversion 4
    set assign-ip enable
    set assign-ip-type ip
    set assign-ip-from range
    set ipv4-start-ip <range_start>
    set ipv4-end-ip <range_end>
    set ipv4-netmask <netmask>
end
```

If your VPN uses IPv6 addresses,

```
config vpn ipsec phase1-interface
edit vpn1
    set mode-cfg-ipversion 6
    set assign-ip enable
    set assign-ip-type ip
    set assign-ip-from range
    set ipv6-start-ip <range_start>
    set ipv6-end-ip <range_end>
end
```

### To assign IP addresses from a RADIUS server

The users must be authenticated by a RADIUS server and assigned to the FortiGate user group <grpname>. Since the IP address will not be static, `type` is set to `dynamic`, and `mode-cfg` is enabled. This is IKE Configuration Method so that compatible clients can configure themselves with settings that the FortiGate unit provides.

```
config vpn ipsec phase1-interface
  edit vpn1
    set type dynamic
    set mode-cfg enable
    set assign-ip enable
    set assign-ip-from usrgroup
    set xauthtype auto
    set authusrgroup <grpname>
  end
```

## Example: FortiGate unit as IKE Mode Config server

In this example, the FortiGate unit assigns IKE Mode Config clients addresses in the range of 10.11.101.160 through 10.11.101.180. DNS and WINS server addresses are also provided. The public interface of the FortiGate unit is Port 1.

The `ipv4-split-include` variable specifies a firewall address that represents the networks to which the clients will have access. This destination IP address information is sent to the clients.

Only the CLI fields required for IKE Mode Config are shown here. For detailed information about these variables, see the [FortiGate CLI Reference](#).

```
config vpn ipsec phase1-interface
  edit vpn1
    set ip-version 4
    set type dynamic
    set interface port1
    set proposal 3des-sha1 aes128-sha1
    set mode-cfg enable
    set mode-cfg-ipversion 4
    set assign-ip enable
    set assign-ip-type ip
    set assign-ip-from range
    set ipv4-start-ip 10.11.101.160
    set ipv4-end-ip 10.11.101.180
    set ipv4-netmask 255.255.255.0
    set dns-server1 10.11.101.199
    set dns-server2 66.11.168.195
    set wins-server1 10.11.101.191
    set domain example
    set ipv4-split-include OfficeLAN
  end
```

## Example: FortiGate unit as IKE Mode Config client

In this example, the FortiGate unit connects to a VPN gateway with a static IP address that can be reached through Port 1. Only the port, gateway and proposal information needs to be configured. All other configuration information will come from the IKE Mode Config server.

```
config vpn ipsec phase1-interface
    edit vpn1
        set ip-version 4
        set type static
        set remote-gw <gw_address>
        set interface port 1
        set proposal 3des-sha1 aes128-sha1
        set mode-cfg enable
        set mode-cfg-ipversion 4
        set assign-ip enable
    end
```

# Internet-browsing configuration

This section explains how to support secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

The following topics are included in this section:

- [Configuration overview](#)
- [Creating an Internet browsing security policy](#)
- [Routing all remote traffic through the VPN tunnel](#)

## Configuration overview

A VPN provides secure access to a private network behind the FortiGate unit. You can also enable VPN clients to access the Internet securely. The FortiGate unit inspects and processes all traffic between the VPN clients and hosts on the Internet according to the Internet browsing policy. This is accomplished even though the same FortiGate interface is used for both encrypted VPN client traffic and unencrypted Internet traffic.

In [Figure 269](#), FortiGate\_1 enables secure Internet browsing for FortiClient Endpoint Security users such as Dialup\_1 and users on the Site\_2 network behind FortiGate\_2, which could be a VPN peer or a dialup client.

**Figure 269:**Example Internet-browsing configuration

You can adapt any of the following configurations to provide secure Internet browsing:

- a gateway-to-gateway configuration (see [“Gateway-to-gateway configurations”](#) on [page 1665](#))
- a FortiClient dialup-client configuration (see [“FortiClient dialup-client configurations”](#) on [page 1709](#))
- a FortiGate dialup-client configuration (see [“FortiGate dialup-client configurations”](#) on [page 1724](#))

The procedures in this section assume that one of these configurations is in place, and that it is operating properly.

To create an internet-browsing configuration based on an existing gateway-to-gateway configuration, you must edit the gateway-to-gateway configuration as follows:

- On the FortiGate unit that will provide Internet access, create an Internet browsing security policy. See [“Creating an Internet browsing security policy”](#), below.
- Configure the remote peer or client to route all traffic through the VPN tunnel. You can do this on a FortiGate unit or on a FortiClient Endpoint Security application. See [“Routing all remote traffic through the VPN tunnel”](#) on page 1739.

## Creating an Internet browsing security policy

On the FortiGate unit that acts as a VPN server and will provide secure access to the Internet, you must create an Internet browsing security policy. This policy differs depending on whether your gateway-to-gateway configuration is policy-based or route-based.

### To create an Internet browsing policy - policy-based VPN

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter the following information and then select *OK*:

<b>Local Interface</b>	The interface to which the VPN tunnel is bound.
<b>Local Protected Subnet</b>	All
<b>Outgoing VPN Interface</b>	The interface to which the VPN tunnel is bound.
<b>Remote Protected Subnet</b>	The internal range of address of the remote spoke site.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the tunnel that provides access to the private network behind the FortiGate unit.
<b>Allow traffic to be initiated from the remote site</b>	Enable
<b>Inbound NAT</b>	Enable

4. Enable inbound NAT in the CLI.

```
config firewall policy
    edit <policy_number>
        set natinbound enable
    end
```

### To create an Internet browsing policy - route-based VPN

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information and then select *OK*:

<b>Incoming Interface</b>	The IPsec VPN interface.
<b>Source Address</b>	All

<b>Outgoing Interface</b>	The interface that connects to the Internet. The virtual IPsec interface is configured on this physical interface.
<b>Destination Address</b>	The internal range of address of the remote spoke site.
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Enable

The VPN clients must be configured to route all Internet traffic through the VPN tunnel.

## Routing all remote traffic through the VPN tunnel

To make use of the Internet browsing configuration on the VPN server, the VPN peer or client must route all traffic through the VPN tunnel. Usually, only the traffic destined for the private network behind the FortiGate VPN server is sent through the tunnel.

The remote end of the VPN can be a FortiGate unit that acts as a peer in a gateway-to-gateway configuration, or a FortiClient application that protects an individual client PC.

- To configure a remote peer FortiGate unit for Internet browsing via VPN, see [“Configuring a FortiGate remote peer to support Internet browsing”](#).
- To configure a FortiClient Endpoint Security application for Internet browsing via VPN, see [“Configuring a FortiClient application to support Internet browsing”](#) on page 1740.

These procedures assume that your VPN connection to the protected private network is working and that you have configured the FortiGate VPN server for Internet browsing as described in [“Creating an Internet browsing security policy”](#) on page 1738.

## Configuring a FortiGate remote peer to support Internet browsing

The configuration changes to send all traffic through the VPN differ for policy-based and route-based VPNs.

### To route all traffic through a policy-based VPN

1. At the FortiGate dialup client, go to *Policy > Policy > Policy*.
2. Select the IPsec security policy and then select *Edit*.
3. From the *Remote Protected Subnet* list, select *all*.
4. Select *OK*.

Packets are routed through the VPN tunnel, not just those destined for the protected private network.

### To route all traffic through a route-based VPN

1. At the FortiGate dialup client, go to *Router > Static > Static Routes*.
2. On a low-end FortiGate unit, go to *System > Network > Routing*.
3. Select the default route (destination IP 0.0.0.0) and then select *Edit*. If there is no default route, select *Create New*. Enter the following information and select *OK*:

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Device</b>	Select the IPsec virtual interface.
<b>Distance</b>	Leave at default.

All packets are routed through the VPN tunnel, not just packets destined for the protected private network.

## Configuring a FortiClient application to support Internet browsing

By default, the FortiClient application configures the PC so that traffic destined for the remote protected network passes through the VPN tunnel but all other traffic is sent to the default gateway. You need to modify the FortiClient settings so that it configures the PC to route all outbound traffic through the VPN.

### To route all traffic through VPN - FortiClient application

1. At the remote host, start FortiClient.
2. Go to *VPN > Connections*.
3. Select the definition that connects FortiClient to the FortiGate dialup server.
4. Select *Advanced* and then select *Edit*.
5. In the *Edit Connection* dialog box, select *Advanced*.
6. In the *Remote Network* group, select *Add*.
7. In the *IP* and *Subnet Mask* fields, type `0.0.0.0/0.0.0.0` and select *OK*.

The address is added to the *Remote Network* list. The first destination IP address in the list establishes a VPN tunnel. The second destination address (`0.0.0.0/0.0.0.0` in this case) forces all other traffic through the VPN tunnel.

8. Select *OK*.

# Redundant VPN configurations

This section discusses the options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches.

The following topics are included in this section:

- [Configuration overview](#)
- [General configuration steps](#)
- [Configure the VPN peers - route-based VPN](#)
- [Redundant route-based VPN configuration example](#)
- [Partially-redundant route-based VPN example](#)
- [Creating a backup IPsec interface](#)

## Configuration overview

A FortiGate unit with two interfaces connected to the Internet can be configured to support redundant VPNs to the same remote peer. If the primary connection fails, the FortiGate unit can establish a VPN using the other connection.

Redundant tunnels do not support Tunnel Mode. You must use Interface Mode.

A fully-redundant configuration requires redundant connections to the Internet on both peers. [Figure 270 on page 1742](#) shows an example of this. This is useful to create a reliable connection between two FortiGate units with static IP addresses.

When only one peer has redundant connections, the configuration is partially-redundant. For an example of this, see [“Partially-redundant route-based VPN example” on page 1758](#). This is useful to provide reliable service from a FortiGate unit with static IP addresses that accepts connections from dialup IPsec VPN clients.

In a fully-redundant VPN configuration with two interfaces on each peer, four distinct paths are possible for VPN traffic from end to end. Each interface on a peer can communicate with both interfaces on the other peer. This ensures that a VPN will be available as long as each peer has one working connection to the Internet.

You configure a VPN and an entry in the routing table for each of the four paths. All of these VPNs are ready to carry data. You set different routing distances for each route and only the shortest distance route is used. If this route fails, the route with the next shortest distance is used.

The redundant configurations described in this chapter use route-based VPNs, otherwise known as virtual IPsec interfaces. This means that the FortiGate unit must operate in NAT mode. You must use auto-keying. A VPN that is created using manual keys (see [“Manual-key configurations” on page 1770](#)) cannot be included in a redundant-tunnel configuration.

The configuration described here assumes that your redundant VPNs are essentially equal in cost and capability. When the original VPN returns to service, traffic continues to use the replacement VPN until the replacement VPN fails. If your redundant VPN uses more expensive facilities, you want to use it only as a backup while the main VPN is down. For information on how to do this, see [“Creating a backup IPsec interface” on page 1765](#).

**Figure 270:**Example redundant-tunnel configuration

A VPN that is created using manual keys (see [“Manual-key configurations”](#) on page 1770) cannot be included in a redundant-tunnel configuration.

## General configuration steps

A redundant configuration at each VPN peer includes:

- one phase 1 configuration (virtual IPsec interface) for each path between the two peers. In a fully-meshed redundant configuration, each network interface on one peer can communicate with each network interface on the remote peer. If both peers have two public interfaces, this means that each peer has four paths, for example.
- one phase 2 definition for each phase 1 configuration
- one static route for each IPsec interface, with different distance values to prioritize the routes
- two Accept security policies per IPsec interface, one for each direction of traffic
- dead peer detection enabled in each phase 1 definition

The procedures in this section assume that two separate interfaces to the Internet are available on each VPN peer.

## Configure the VPN peers - route-based VPN

VPN peers are configured using Interface Mode for redundant tunnels.

Configure each VPN peer as follows:

1. Ensure that the interfaces used in the VPN have static IP addresses.

2. Create a phase 1 configuration for each of the paths between the peers. Enable IPsec Interface mode so that this creates a virtual IPsec interface. Enable dead peer detection so that one of the other paths is activated if this path fails.

Enter these settings in particular, and any other VPN settings as required:

#### Path 1

<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Type the IP address of the primary interface of the remote peer.
<b>Local Interface</b>	Select the primary public interface of this peer.
<b>Enable IPsec Interface Mode</b>	Enable
<b>Dead Peer Detection</b>	Enable

#### Path 2

<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Type the IP address of the secondary interface of the remote peer.
<b>Local Interface</b>	Select the primary public interface of this peer.
<b>Enable IPsec Interface Mode</b>	Enable
<b>Dead Peer Detection</b>	Enable

#### Path 3

<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Type the IP address of the primary interface of the remote peer.
<b>Local Interface</b>	Select the secondary public interface of this peer.
<b>Enable IPsec Interface Mode</b>	Enable
<b>Dead Peer Detection</b>	Enable

#### Path 4

<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Type the IP address of the secondary interface of the remote peer.
<b>Local Interface</b>	Select the secondary public interface of this peer.
<b>Enable IPsec Interface Mode</b>	Enable
<b>Dead Peer Detection</b>	Enable

For more information, see [“Auto Key phase 1 parameters” on page 1637](#).

3. Create a phase 2 definition for each path. See [“Phase 2 parameters” on page 1653](#). Select the phase 1 configuration (virtual IPsec interface) that you defined for this path. You can select the name from the Static IP Address part of the list.
4. Create a route for each path to the other peer. If there are two ports on each peer, there are four possible paths between the peer devices.

---

<b>Destination IP/Mask</b>	The IP address and netmask of the private network behind the remote peer.
----------------------------	---

---

<b>Device</b>	One of the virtual IPsec interfaces on the local peer.
---------------	--

---

<b>Distance</b>	For each path, enter a different value to prioritize the paths.
-----------------	---

---

5. Define the security policy for the local primary interface. See [“Defining VPN security policies” on page 1660](#). You need to create two policies for each path to enable communication in both directions. Enter these settings in particular:

---

<b>Incoming Interface</b>	Select the local interface to the internal (private) network.
---------------------------	---

---

<b>Source Address</b>	All
-----------------------	-----

---

<b>Outgoing Interface</b>	Select one of the virtual IPsec interfaces you created in <a href="#">Step 2</a> .
---------------------------	--

---

<b>Destination Address</b>	All
----------------------------	-----

---

<b>Schedule</b>	Always
-----------------	--------

---

<b>Service</b>	Any
----------------	-----

---

<b>Action</b>	ACCEPT
---------------	--------

---

6. Select *Create New*, leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*, and enter these settings:

---

<b>Incoming Interface</b>	Select one of the virtual IPsec interfaces you created in <a href="#">Step 2</a> .
---------------------------	--

---

<b>Source Address</b>	All
-----------------------	-----

---

<b>Outgoing Interface</b>	Select the local interface to the internal (private) network.
---------------------------	---

---

<b>Destination Address</b>	All
----------------------------	-----

---

<b>Schedule</b>	Always
-----------------	--------

---

<b>Service</b>	Any
----------------	-----

---

<b>Action</b>	ACCEPT
---------------	--------

---

7. Place the policy in the policy list above any other policies having similar source and destination addresses.
8. Repeat this procedure at the remote FortiGate unit.

## Redundant route-based VPN configuration example

This example demonstrates a fully redundant site-to-site VPN configuration using route-based VPNs. At each site, the FortiGate unit has two interfaces connected to the Internet through different ISPs. This means that there are four possible paths for communication between the two units. In this example, these paths, listed in descending priority, are:

- FortiGate\_1 WAN 1 to FortiGate\_2 WAN 1
- FortiGate\_1 WAN 1 to FortiGate\_2 WAN 2
- FortiGate\_1 WAN 2 to FortiGate\_2 WAN 1
- FortiGate\_1 WAN 2 to FortiGate\_2 WAN 2

**Figure 271:**Example redundant route-based VPN configuration

For each path, VPN configuration, security policies and routing are defined. By specifying a different routing distance for each path, the paths are prioritized. A VPN tunnel is established on each path, but only the highest priority one is used. If the highest priority path goes down, the traffic is automatically routed over the next highest priority path. You could use dynamic routing, but to keep this example simple, static routing is used.

### Configuring FortiGate\_1

You must

- configure the interfaces involved in the VPN
- define the phase 1 configuration for each of the four possible paths, creating a virtual IPsec interface for each one
- define the phase 2 configuration for each of the four possible paths
- configure routes for the four IPsec interfaces, assigning the appropriate priorities
- configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces

#### To configure the network interfaces

1. Go to *System > Network > Interfaces*.
2. Select the Internal interface and select *Edit*.

3. Enter the following information and then select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Netmask</b>	10.21.101.0/255.255.255.0

4. Select the WAN1 interface and select *Edit*, enter the following information and then select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Netmask</b>	192.168.10.2/255.255.255.0

5. Select the WAN2 interface and select *Edit*, enter the following information and then select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Netmask</b>	172.16.20.2/255.255.255.0

**To configure the IPsec interfaces (phase 1 configurations)**

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_1_A
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	192.168.20.2
<b>Local Interface</b>	WAN1
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

3. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_1_B
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	172.16.30.2
<b>Local Interface</b>	WAN1

<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

- 4 Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_1_C
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	192.168.20.2
<b>Local Interface</b>	WAN2
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

5. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_1_D
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	172.16.30.2
<b>Local Interface</b>	WAN2
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	

<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

### To define the phase 2 configurations for the four VPNs

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_A
<b>Phase 1</b>	Site_1_A

3. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_B
<b>Phase 1</b>	Site_1_B

4. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_C
<b>Phase 1</b>	Site_1_C

5. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_D
<b>Phase 1</b>	Site_1_D

### To configure routes

1. Go to *Router > Static > Static Routes*.  
For low-end FortiGate units, go to *System > Network > Routing*.
2. Select *Create New*, enter the following default gateway information and then select *OK*:

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Device</b>	WAN1
<b>Gateway</b>	192.168.10.1
<b>Distance (Advanced)</b>	10

3. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.31.101.0/255.255.255.0
<b>Device</b>	Site_1_A
<b>Distance (Advanced)</b>	1

4. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.31.101.0/255.255.255.0
<b>Device</b>	Site_1_B
<b>Distance (Advanced)</b>	2

5. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.31.101.0/255.255.255.0
<b>Device</b>	Site_1_C
<b>Distance (Advanced)</b>	3

6. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.31.101.0/255.255.255.0
<b>Device</b>	Site_1_D
<b>Distance (Advanced)</b>	4

#### To configure security policies

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and then select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_1_A
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
6. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Site_1_A
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Internal
<b>Destination Address</b>	All

<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

7. Select *Create New*.
8. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
9. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_1_B
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

10. Select *Create New*.
11. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
12. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Site_1_B
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Internal
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

13. Select *Create New*.
14. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
15. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_1_C
<b>Destination Address</b>	All
<b>Schedule</b>	Always

<b>Service</b>	Any
<b>Action</b>	ACCEPT

16. Select *Create New*.

17. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

18. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Site_1_C
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Internal
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

19. Select *Create New*.

20. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

21. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_1_D
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

22. Select *Create New*.

23. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

24. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Site_1_D
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Internal
<b>Destination Address</b>	All
<b>Schedule</b>	Always

<b>Service</b>	Any
<b>Action</b>	ACCEPT

## Configuring FortiGate\_2

The configuration for FortiGate\_2 is very similar that of FortiGate\_1. You must

- configure the interfaces involved in the VPN
- define the phase 1 configuration for each of the four possible paths, creating a virtual IPsec interface for each one
- define the phase 2 configuration for each of the four possible paths
- configure routes for the four IPsec interfaces, assigning the appropriate priorities
- configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces

### To configure the network interfaces

1. Go to *System > Network > Interfaces*.
2. Select the Internal interface and then select *Edit*. Enter the following information and then select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Netmask</b>	10.31.101.0/255.255.255.0

3. Select the WAN1 interface and then select *Edit*. Enter the following information and then select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Netmask</b>	192.168.20.2/255.255.255.0

4. Select the WAN2 interface and then select *Edit*. Enter the following information and then select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Netmask</b>	172.16.30.2/255.255.255.0

### To configure the IPsec interfaces (phase 1 configurations)

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_2_A
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	192.168.10.2
<b>Local Interface</b>	WAN1
<b>Mode</b>	Main

<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

3. Select *Create Phase 1*, enter the following information, and select **OK**:

<b>Name</b>	Site_2_B
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	172.16.20.2
<b>Local Interface</b>	WAN1
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

4. Select *Create Phase 1*, enter the following information, and select **OK**:

<b>Name</b>	Site_2_C
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	192.168.10.2
<b>Local Interface</b>	WAN1
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

5. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_2_D
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	172.16.20.2
<b>Local Interface</b>	WAN1
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

#### To define the phase 2 configurations for the four VPNs

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_A
<b>Phase 1</b>	Site_2_A

3. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_B
<b>Phase 1</b>	Site_2_B

4. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_C
<b>Phase 1</b>	Site_2_C

5. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_D
<b>Phase 1</b>	Site_2_D

#### To configure routes

1. Go to *Router > Static > Static Routes*.  
For low-end FortiGate units, go to *System > Network > Routing*.

2. Select *Create New*, enter the following default gateway information and then select *OK*:

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Device</b>	WAN1
<b>Gateway</b>	192.168.10.1
<b>Distance (Advanced)</b>	10

3. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.21.101.0/255.255.255.0
<b>Device</b>	Site_2_A
<b>Distance (Advanced)</b>	1

4. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.21.101.0/255.255.255.0
<b>Device</b>	Site_2_B
<b>Distance (Advanced)</b>	2

5. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.21.101.0/255.255.255.0
<b>Device</b>	Site_2_C
<b>Distance (Advanced)</b>	3

6. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.21.101.0/255.255.255.0
<b>Device</b>	Site_2_D
<b>Distance (Advanced)</b>	4

#### To configure security policies

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_2_A
<b>Destination Address</b>	All

<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
6. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Site_2_A
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Internal
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

7. Select *Create New*.
8. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
9. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_2_B
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

10. Select *Create New*.
11. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
12. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Site_2_B
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Internal
<b>Destination Address Name</b>	All
<b>Schedule</b>	Always

<b>Service</b>	Any
<b>Action</b>	ACCEPT

13. Select *Create New*.

14. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

15. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_2_C
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

16. Select *Create New*.

17. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

18. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Site_2_C
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Internal
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

19. Select *Create New*.

20. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

21. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_2_D
<b>Destination Address</b>	All
<b>Schedule</b>	Always

<b>Service</b>	Any
<b>Action</b>	ACCEPT

22. Select *Create New*.

23. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

24. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Site_2_D
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Internal
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

## Partially-redundant route-based VPN example

This example demonstrates how to set up a partially redundant IPsec VPN between a local FortiGate unit and a remote VPN peer that receives a dynamic IP address from an ISP before it connects to the FortiGate unit. For more information about FortiGate dialup-client configurations, see [“FortiGate dialup-client configurations” on page 1724](#).

When a FortiGate unit has more than one interface to the Internet (see FortiGate\_1 in [Figure 272](#)), you can configure redundant routes. If the primary connection fails, the FortiGate unit can establish a VPN using the redundant connection.

In this case, FortiGate\_2 has only one connection to the Internet. If the link to the ISP were to go down, the connection to FortiGate\_1 would be lost, and the tunnel would be taken down. The tunnel is said to be partially redundant because FortiGate\_2 does not support a redundant connection.

In the configuration example:

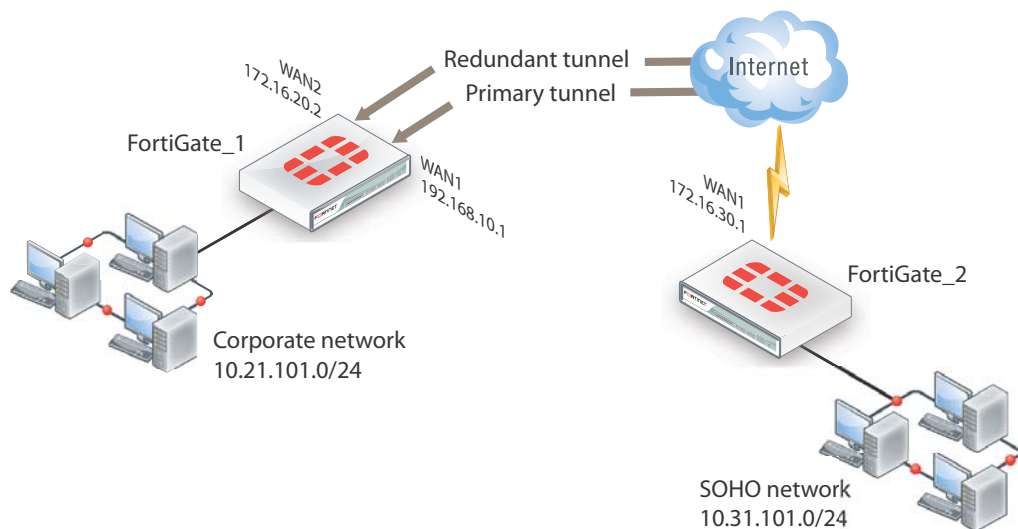

- Both FortiGate units operate in NAT mode.
- Two separate interfaces to the Internet (192.168.10.2 and 172.16.20.2) are available on FortiGate\_1. Each interface has a static public IP address.
- FortiGate\_2 has a single connection to the Internet and obtains a dynamic public IP address (for example, 172.16.30.1) when it connects to the Internet.
- FortiGate\_2 forwards IP packets from the SOHO network (10.31.101.0/24) to the corporate network (10.21.101.0/24) behind FortiGate\_1 through a partially redundant IPsec VPN. Encrypted packets from FortiGate\_2 are addressed to the public interface of FortiGate\_1. Encrypted packets from FortiGate\_1 are addressed to the public IP address of FortiGate\_2.

There are two possible paths for communication between the two units. In this example, these paths, listed in descending priority, are:

- FortiGate\_1 WAN 1 to FortiGate\_2 WAN 1
- FortiGate\_1 WAN 2 to FortiGate\_2 WAN 1

For each path, VPN configuration, security policies and routing are defined. By specifying a different routing distance for each path, the paths are prioritized. A VPN tunnel is established on each path, but only the highest priority one is used. If the highest priority path goes down, the traffic is automatically routed over the next highest priority path. You could use dynamic routing, but to keep this example simple, static routing is used.

**Figure 272:**Example partially redundant route-based configuration

## Configuring FortiGate\_1

You must

- configure the interfaces involved in the VPN
- define the phase 1 configuration for each of the two possible paths, creating a virtual IPsec interface for each one
- define the phase 2 configuration for each of the two possible paths
- configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces

### To configure the network interfaces

1. Go to *System > Network > Interfaces*.
2. Select the Internal interface and select *Edit*. Enter the following information and select *OK*:

Addressing mode	Manual
IP/Netmask	10.21.101.2/255.255.255.0

3. Select the WAN1 interface and select *Edit*. Enter the following information and select *OK*:

Addressing mode	Manual
IP/Netmask	192.168.10.2/255.255.255.0

4. Select the WAN2 interface and select *Edit*. Enter the following information and select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Netmask</b>	172.16.20.2/255.255.255.0

**To configure the IPsec interfaces (phase 1 configurations)**

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_1_A
<b>Remote Gateway</b>	Dialup User
<b>Local Interface</b>	WAN1
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

3. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_1_B
<b>Remote Gateway</b>	Dialup User
<b>Local Interface</b>	WAN2
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

### To define the phase 2 configurations for the two VPNs

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_A
<b>Phase 1</b>	Site_1_A

3. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_B
<b>Phase 1</b>	Site_1_B

### To configure routes

1. Go to *Router > Static > Static Routes*.  
For low-end FortiGate units, go to *System > Network > Routing*.
2. Select *Create New*, enter the following default gateway information and select *OK*:

<b>Destination IP/Mask</b>	0.0.0.0/0.0.0.0
<b>Device</b>	WAN1
<b>Gateway</b>	192.168.10.1
<b>Distance (Advanced)</b>	10

### To configure security policies

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_1_A
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
6. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All

<b>Outgoing Interface</b>	Site_1_B
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

## Configuring FortiGate\_2

The configuration for FortiGate\_2 is similar to that of FortiGate\_1. You must

- configure the interface involved in the VPN
- define the phase 1 configuration for the primary and redundant paths, creating a virtual IPsec interface for each one
- define the phase 2 configurations for the primary and redundant paths, defining the internal network as the source address so that FortiGate\_1 can automatically configure routing
- configure the routes for the two IPsec interfaces, assigning the appropriate priorities
- configure security policies between the internal interface and each of the virtual IPsec interfaces

### To configure the network interfaces

1. Go to *System > Network > Interfaces*.
2. Select the Internal interface and select *Edit*. Enter the following information and select *OK*:

<b>Addressing mode</b>	Manual
<b>IP/Netmask</b>	10.31.101.2/255.255.255.0

3. Select the WAN1 interface and select *Edit*. Set the *Addressing mode* to *DHCP*.

### To configure the two IPsec interfaces (phase 1 configurations)

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_2_A
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	192.168.10.2
<b>Local Interface</b>	WAN1
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	

<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

3. Select *Create Phase 1*, enter the following information, and select *OK*:

<b>Name</b>	Site_2_B
<b>Remote Gateway</b>	Static IP Address
<b>IP Address</b>	172.16.20.2
<b>Local Interface</b>	WAN1
<b>Mode</b>	Main
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key.
<b>Peer Options</b>	Accept any peer ID
<b>Advanced</b>	
<b>Enable IPsec Interface Mode</b>	Select
<b>Dead Peer Detection</b>	Select

#### To define the phase 2 configurations for the two VPNs

1. Go to *VPN > IPsec > Auto Key (IKE)*.
2. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_A
<b>Phase 1</b>	Site_2_A
<b>Advanced</b>	
<b>Source Address</b>	10.31.101.0/24

3. Select *Create Phase 2*, enter the following information and select *OK*:

<b>Name</b>	Route_B
<b>Phase 1</b>	Site_2_B
<b>Advanced</b>	
<b>Source Address</b>	10.31.101.0/24

#### To configure routes

1. Go to *Router > Static > Static Routes*.  
For low-end FortiGate units, go to *System > Network > Routing*.

2. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.21.101.0/255.255.255.0
<b>Device</b>	Site_2_A
<b>Distance (Advanced)</b>	1

3. Select *Create New*, enter the following information and then select *OK*:

<b>Destination IP/Mask</b>	10.21.101.0/255.255.255.0
<b>Device</b>	Site_2_B
<b>Distance (Advanced)</b>	2

### To configure security policies

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_2_A
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

4. Select *Create New*.
5. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
6. Enter the following information, and select *OK*:

<b>Incoming Interface</b>	Internal
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Site_2_B
<b>Destination Address</b>	All
<b>Schedule</b>	Always
<b>Service</b>	Any
<b>Action</b>	ACCEPT

## Creating a backup IPsec interface

You can configure a route-based VPN that acts as a backup facility to another VPN. It is used only while your main VPN is out of service. This is desirable when the redundant VPN uses a more expensive facility.

You can configure a backup IPsec interface only in the CLI. The backup feature works only on interfaces with static addresses that have dead peer detection enabled. The `monitor` option creates a backup VPN for the specified phase 1 configuration.

In the following example, `backup_vpn` is a backup for `main_vpn`.

```
config vpn ipsec phase1-interface
  edit main_vpn
    set dpd on
    set interface port1
    set nattraversal enable
    set psksecret "hard-to-guess"
    set remote-gw 192.168.10.8
    set type static
  end
  edit backup_vpn
    set dpd on
    set interface port2
    set monitor main_vpn
    set nattraversal enable
    set psksecret "hard-to-guess"
    set remote-gw 192.168.10.8
    set type static
  end
end
```

# Transparent mode VPNs

This section describes transparent VPN configurations, in which two FortiGate units create a VPN tunnel between two separate private networks transparently.

The following topics are included in this section:

- [Configuration overview](#)
- [Configure the VPN peers](#)

## Configuration overview

In transparent mode, all interfaces of the FortiGate unit except the management interface (which by default is assigned IP address 10.10.10.1/255.255.255.0) are invisible at the network layer. Typically, when a FortiGate unit runs in transparent mode, different network segments are connected to the FortiGate interfaces. [Figure 273](#) shows the management station on the same subnet. The management station can connect to the FortiGate unit directly through the web-based manager.

**Figure 273:**Management station on internal network

An edge router typically provides a public connection to the Internet and one interface of the FortiGate unit is connected to the router. If the FortiGate unit is managed from an external address (see [Figure 274 on page 1767](#)), the router must translate (NAT) a routable address to direct management traffic to the FortiGate management interface.

**Figure 274:**Management station on external network

In a transparent VPN configuration, two FortiGate units create a VPN tunnel between two separate private networks transparently. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Both FortiGate units may be running in transparent mode, or one could be running in transparent mode and the other running in NAT mode. If the remote peer is running in NAT mode, it must have a static public IP address.

VPNs between two FortiGate units running in transparent mode do not support inbound/outbound NAT (supported through CLI commands) within the tunnel. In addition, a FortiGate unit running in transparent mode cannot be used in a hub-and-spoke configuration.

Encrypted packets from the remote VPN peer are addressed to the management interface of the local FortiGate unit. If the local FortiGate unit can reach the VPN peer locally, a static route to the VPN peer must be added to the routing table on the local FortiGate unit. If the VPN peer connects through the Internet, encrypted packets from the local FortiGate unit must be routed to the edge router instead. For information about how to add a static route to the FortiGate routing table, see the [Advanced Routing](#).

In the example configuration shown in [Figure 274](#), Network Address Translation (NAT) is enabled on the router. When an encrypted packet from the remote VPN peer arrives at the router through the Internet, the router performs inbound NAT and forwards the packet to the FortiGate unit. Refer to the software supplier's documentation to configure the router.

If you want to configure a VPN between two FortiGate units running in transparent mode, each unit must have an independent connection to a router that acts as a gateway to the Internet, and both units must be on separate networks that have a different address space. When the two networks linked by the VPN tunnel have different address spaces (see [Figure 275 on page 1768](#)), at least one router must separate the two FortiGate units, unless the packets can be redirected using ICMP (see [Figure 276 on page 1768](#)).

**Figure 275:**Link between two FortiGate units in transparent mode

In [Figure 276](#), interface C behind the router is the default gateway for both FortiGate units. Packets that cannot be delivered on Network\_1 are routed to interface C by default. Similarly, packets that cannot be delivered on Network\_2 are routed to interface C. In this case, the router must be configured to redirect packets destined for Network\_1 to interface A and redirect packets destined for Network\_2 to interface B.

**Figure 276:**ICMP redirecting packets to two FortiGate units in transparent mode

If there are additional routers behind the FortiGate unit (see [Figure 277 on page 1769](#)) and the destination IP address of an inbound packet is on a network behind one of those routers, the FortiGate routing table must include routes to those networks. For example, in [Figure 277](#), the FortiGate unit must be configured with static routes to interfaces A and B in order to forward packets to Network\_1 and Network\_2 respectively.

**Figure 277:**Destinations on remote networks behind internal routers

## Transparent VPN infrastructure requirements

- The local FortiGate unit must be operating in transparent mode.
- The management IP address of the local FortiGate unit specifies the local VPN gateway. The management IP address is considered a static IP address for the local VPN peer.
- If the local FortiGate unit is managed through the Internet, or if the VPN peer connects through the Internet, the edge router must be configured to perform inbound NAT and forward management traffic and/or encrypted packets to the FortiGate unit.
- If the remote peer is operating in NAT mode, it must have a static public IP address.

A FortiGate unit operating in transparent mode requires the following basic configuration to operate as a node on the IP network:

- The unit must have sufficient routing information to reach the management station.
- For any traffic to reach external destinations, a default static route to an edge router that forwards packets to the Internet must be present in the FortiGate routing table.
- When all of the destinations are located on the external network, the FortiGate unit may route packets using a single default static route. If the network topology is more complex, one or more static routes in addition to the default static route may be required in the FortiGate routing table.

Only policy-based VPN configurations are possible in transparent mode.

## Before you begin

An IPsec VPN definition links a gateway with a tunnel and an IPsec policy. If your network topology includes more than one virtual domain, you must choose components that were created in the same virtual domain. Therefore, before you define a transparent VPN configuration, choose an appropriate virtual domain in which to create the required interfaces, security policies, and VPN components. For more information, see the [Virtual Domains](#) chapter of *The Handbook*.

## Configure the VPN peers

1. The local VPN peer need to operate in transparent mode.

To determine if your FortiGate unit is in transparent mode, go to *System > Dashboard > Status to the System Information* widget. Select *[change]*. Select transparent for the *Operation Mode*. Two new fields will appear to enter the *Management IP/Netmask*, and the *Default Gateway*.

In transparent mode, the FortiGate unit is invisible to the network. All of its interfaces are on the same subnet and share the same IP address. You only have to configure a management IP address so that you can make configuration changes.

The remote VPN peer may operate in NAT mode or transparent mode.

2. At the local FortiGate unit, define the phase 1 parameters needed to establish a secure connection with the remote peer. See [“Auto Key phase 1 parameters” on page 1637](#). Select *Advanced* and enter these settings in particular:

<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Type the IP address of the public interface to the remote peer. If the remote peer is a FortiGate unit running in transparent mode, type the IP address of the remote management interface.
<b>Advanced</b>	Select <i>Nat-traversal</i> , and type a value into the <i>Keepalive Frequency</i> field. These settings protect the headers of encrypted packets from being altered by external NAT devices and ensure that NAT address mappings do not change while the VPN tunnel is open. For more information, see <a href="#">“NAT traversal” on page 1649</a> and <a href="#">“NAT keepalive frequency” on page 1650</a> .

3. Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. See [“Phase 2 parameters” on page 1653](#). Select the set of phase 1 parameters that you defined for the remote peer. The name of the remote peer can be selected from the *Static IP Address* list.
4. Define the source and destination addresses of the IP packets that are to be transported through the VPN tunnel. See [“Defining policy addresses” on page 1659](#). Enter these settings in particular:
  - For the originating address (source address), enter the IP address and netmask of the private network behind the local peer network. for the management interface, for example, 10.10.10.0/24. This address needs to be a range to allow traffic from your network through the tunnel. Optionally select *any* for this address.
  - For the remote address (destination address), enter the IP address and netmask of the private network behind the remote peer (for example, 192.168.10.0/24). If the remote peer is a FortiGate unit running in transparent mode, enter the IP address of the remote management interface instead.
5. Define an IPsec security policy to permit communications between the source and destination addresses. See [“Defining VPN security policies” on page 1660](#). Enter these settings in particular:

<b>Local Interface</b>	Select the local interface to the internal (private) network.
<b>Local Protected Subnet</b>	Select the source address that you defined in Step 4.

<b>Outgoing VPN Interface</b>	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
<b>Remote Protected Subnet</b>	Select the destination address that you defined in Step 4.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the name of the phase 2 tunnel configuration that you created in Step 3 from the drop-down list.  Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.

- Place the policy in the policy list above any other policies having similar source and destination addresses.
- Define another IPsec security policy to permit communications between the source and destination addresses in the opposite direction. This security policy and the previous one form a bi-directional policy pair. See [“Defining VPN security policies” on page 1660](#). Enter these settings in particular:

<b>Local Interface</b>	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
<b>Local Protected Subnet</b>	Select the destination address that you defined in Step 4.
<b>Outgoing VPN Interface</b>	Select the local interface to the internal (private) network.
<b>Remote Protected Subnet</b>	Select the source address that you defined in Step 4.
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the name of the phase 2 tunnel configuration that you created in Step 3 from the drop-down list.  Select <i>Allow traffic to be initiated from the remote site</i> to enable traffic from the remote network to initiate the tunnel.

- Repeat this procedure at the remote FortiGate unit to create bidirectional security policies. Use the local interface and address information local to the remote FortiGate unit.

For more information on transparent mode, see the [System Administration Guide handbook chapter](#).

# IPv6 IPsec VPNs

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations do not appear on the Web-based Manager. You need to enable the feature first.

## To enable IPv6

1. Go to *System > Admin > Settings*.
2. In the *Display Options on GUI* section, select *IPv6*.
3. Select *Apply*.

The following topics are included in this section:

- [Overview of IPv6 IPsec support](#)
- [Configuring IPv6 IPsec VPNs](#)
- [Site-to-site IPv6 over IPv6 VPN example](#)
- [Site-to-site IPv4 over IPv6 VPN example](#)
- [Site-to-site IPv6 over IPv4 VPN example](#)

## Overview of IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support. FortiOS 4.0 MR3 is IPv6 Ready Logo Program Phase 2 certified.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

<b>IPv4 over IPv6</b>	The VPN gateways have IPv6 addresses.  The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors.
<b>IPv6 over IPv4</b>	The VPN gateways have IPv4 addresses.  The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- You cannot use RSA certificates in which the common name (cn) is a domain name that resolves to an IPv6 address. This is because FortiOS 3.0 does not support IPv6 DNS.
- DHCP over IPsec is not supported, because FortiOS 3.0 does not support IPv6 DHCP.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

## Certificates

On a VPN with IPv6 phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

## Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN: phase 1 settings, phase 2 settings, security policies and routing.

By default IPv6 configurations do not appear on the Web-based Manager. You need to enable the feature first.

### To enable IPv6

1. Go to *System > Admin > Settings*.
2. In the *Display Options on GUI* section, select *IPv6*.
3. Select *Apply*.

## Phase 1 configuration

In the web-based manager, you define the Phase 1 as IPv6 in the Advanced settings. Enable the IPv6 Version check box. You can then enter an IPv6 address for the remote gateway.

In the CLI, you define an IPsec phase 1 configuration as IPv6 by setting `ip-version` to 6. Its default value is 4. Then, the `local-gw` and `remote-gw` keywords are hidden and the corresponding `local-gw6` and `remote-gw6` keywords are available. The values for `local-gw6` and `remote-gw6` must be IPv6 addresses. For example:

```
config vpn ipsec phase1-interface
edit tunnel6
set ip-version 6
set remote-gw6 0:123:4567::1234
set interface port3
set proposal 3des-md5
end
```

## Phase 2 configuration

To create an IPv6 IPsec phase 2 configuration in the web-based manager, you need to define IPv6 selectors in the Advanced settings. Change the default “0.0.0.0/0” address for Source address and Destination address to the IPv6 value “::/0”. If needed, enter specific IPv6 addresses, address ranges or subnet addresses in these fields.

In the CLI, set `src-addr-type` and `dst-addr-type` to `ip6`, `range6` or `subnet6` to specify IPv6 selectors. By default, zero selectors are entered, “`::/0`” for the `subnet6` address type, for example. The simplest IPv6 phase 2 configuration looks like this:

```
config vpn ipsec phase2-interface
edit tunnel6_p2
set phase1name tunnel6
set proposal 3des-md5
set src-addr-type subnet6
set dst-addr-type subnet6
end
```

## Security policies

To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network’s port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6.

## Routing

Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them. You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You also need a route to the remote protected network via the IPsec interface.

To create a static route in the web-based manager

1. Go to *Router > Static > Static Routes*.  
On low-end FortiGate units, go to *System > Network > Routing*.
2. Select the drop-down arrow on the *Create New* button and select *IPv6 Route*.
3. Enter the information and select *OK*.

In the CLI, use the `router static6` command. For example, where the remote network is `fec0:0000:0000:0004::/64` and the IPsec interface is `toB`:

```
config router static6
edit 1
set device port2
set dst 0::/0
next
edit 2
set device toB
set dst fec0:0000:0000:0004::/64
next
end
```

If the VPN is IPv4 over IPv6, the route to the remote protected network is an IPv4 route. If the VPN is IPv6 over IPv4, the route to the remote VPN gateway is an IPv4 route.

## Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

To access IPv6 functionality through the web-based manager, go to *System Admin > Settings* and enable *IPv6* in the section, *Display Options on GUI*.

**Figure 278:**Example IPv6-over-IPv6 VPN topology

## Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
  edit port3
    config ipv6
      set ip6-address fec0::0000:209:0fff:fe83:25f3/64
    end
  next
end
```

## Configure FortiGate A IPsec settings

The phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4

route-based VPN, except that `ip-version` is set to 6 and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```
config vpn ipsec phase1-interface
edit toB
set ip-version 6
set interface port2
set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
set dpd enable
set psksecret maryhadalittlelamb
set proposal 3des-md5 3des-sha1
end
```

By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, ::/0 for IPv6.

```
config vpn ipsec phase2-interface
edit toB2
set phase1name toB
set proposal 3des-md5 3des-sha1
set pfs enable
set replay enable
set src-addr-type subnet6
set dst-addr-type subnet6
end
```

## Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as ::/0.

```
config firewall policy6
edit 1
set srcintf port3
set dstintf toB
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
next
edit 2
set srcintf toB
set dstintf port3
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
end
```

## Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toB
    set dst fec0:0000:0000:0004::/64
  end
```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0003:209:0fff:fe83:25c7/64
    end
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
  end
config vpn ipsec phase1-interface
  edit toA
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
```

```

end
config firewall policy6
edit 1
set srcintf port3
set dstintf toA
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
next
edit 2
set srcintf toA
set dstintf port3
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
end
config router static6
edit 1
set device port2
set dst 0::/0
next
edit 2
set device toA
set dst fec0:0000:0000:0000::/64
end

```

## Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

**Figure 279:**Example IPv4-over-IPv6 VPN topology

## Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
  edit port3
    set 192.168.2.1/24
  end
```

## Configure FortiGate A IPsec settings

The phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The phase 2 configuration is the same as you would use for an IPv4 VPN. By default, phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
  end
```

## Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
```

```

next
edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
end

```

## Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```

config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toB
        set dst 192.168.3.0/24
    end
end

```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

```

config system interface
    edit port2
        config ipv6
            set ip6-address fec0::0003:fe83:25c7/64
        end
    next
    edit port3
        set 192.168.3.1/24
    end
config vpn ipsec phase1-interface
    edit toA
        set ip-version 6
        set interface port2
        set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
        set dpd enable
    end
end

```

```

        set psksecret maryhadalittlelamb
        set proposal 3des-md5 3des-sha1
    end
config vpn ipsec phase2-interface
    edit toA2
        set phase1name toA
        set proposal 3des-md5 3des-sha1
        set pfs enable
        set replay enable
    end
config firewall policy
    edit 1
        set srcintf port3
        set dstintf toA
        set srcaddr all
        set dstaddr all
        set action accept
        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toA
        set dstintf port3
        set srcaddr all
        set dstaddr all
        set action accept
        set service ANY
        set schedule always
    end
config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toA
        set dst 192.168.2.0/24
    end
end

```

## Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

**Figure 280:**Example IPv6-over-IPv4 VPN topology

### Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
  edit port2
    set 10.0.0.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f3/64
    end
  end
```

### Configure FortiGate A IPsec settings

The phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
  edit toB
    set interface port2
    set remote-gw 10.0.1.1
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The phase 2 configuration uses IPv6 selectors. By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, :::/0 for IPv6.

```

config vpn ipsec phase2-interface
edit toB2
set phase1name toB
set proposal 3des-md5 3des-sha1
set pfs enable
set replay enable
set src-addr-type subnet6
set dst-addr-type subnet6
end

```

## Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. Define the address all6 using the `firewall address6` command as `::/0`.

```

config firewall policy6
edit 1
set srcintf port3
set dstintf toB
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
next
edit 2
set srcintf toB
set dstintf port3
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
end

```

## Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on port2.

```

config router static6
edit 1
set device toB
set dst fec0:0000:0000:0004::/64
end
config router static
edit 1
set device port2
set dst 0.0.0.0/0
set gateway 10.0.0.254
end

```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
  edit port2
    set 10.0.1.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
config vpn ipsec phase1-interface
  edit toA
    set interface port2
    set remote-gw 10.0.0.1
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all6
    set dstaddr all6
    set action accept
```

```
        set service ANY
        set schedule always
    end
config router static6
    edit 1
        set device toA
        set dst fec0:0000:0000:0000::/64
    end
config router static
    edit 1
        set device port2
        set gateway 10.0.1.254
    end
```

# L2TP and IPsec (Microsoft VPN)

This section describes how to set up a VPN that is compatible with the Microsoft Windows native VPN, which is Layer 2 Tunneling Protocol (L2TP) with IPsec encryption.

The following topics are included in this section:

- [Overview](#)
- [Assumptions](#)
- [Configuring the FortiGate unit](#)
- [Configuring the Windows PC](#)
- [Troubleshooting](#)

## Overview

The topology of a VPN for Microsoft Windows dialup clients is very similar to the topology for FortiClient Endpoint Security clients.

**Figure 281:**Example FortiGate VPN configuration with Microsoft clients

For users, the difference is that instead of installing and using the FortiClient application, they configure a network connection using the software built into the Microsoft Windows operating system. Starting in FortiOS 4.0 MR2, you can configure a FortiGate unit to work with unmodified Microsoft VPN client software.

## Layer 2 Tunneling Protocol (L2TP)

L2TP is a tunneling protocol published in 1999 that is used with VPNs, as the name suggests. Microsoft Windows operating system has a built-in L2TP client starting since Windows 2000. Mac OS X 10.3 system and higher also have a built-in client.

L2TP provides no encryption and used UDP port 1701. IPsec is used to secure L2TP packets. The initiator of the L2TP tunnel is called the L2TP Access Concentrator (LAC).

L2TP and IPsec is supported for native Windows XP, Windows Vista and Mac OSX native VPN clients. However, in Mac OSX (OSX 10.6.3, including patch releases) the L2TP feature does not work properly on the Mac OS side.

## Assumptions

The following assumptions have been made for this example:

- L2TP protocol traffic is allowed through network firewalls (TCP and UDP port 1701)
- User has Microsoft Windows 2000 or higher — a Windows version that supports L2TP

## Configuring the FortiGate unit

To configure the FortiGate unit, you need to:

- configure L2TP users and firewall user group;
- configure the L2TP VPN, including the IP address range it assigns to clients;
- configure an IPsec VPN with encryption and authentication settings that match the Microsoft VPN client;
- configure security policies.

### Configuring L2TP users and firewall user group

Remote users must be authenticated before they can request services and/or access network resources through the VPN. The authentication process can use a password defined on the FortiGate unit or an established external authentication mechanism such as RADIUS or LDAP.

#### Creating user accounts

You need to create user accounts and then add these users to a firewall user group to be used for L2TP authentication. The Microsoft VPN client can automatically send the user's Windows network logon credentials. You might want to use these for their L2TP user name and password.

##### To create a user account - web-based manager

1. Go to *User & Device > User > User Definition* and select *Create New*.
2. Enter the *User Name*.
3. Do one of the following:
  - Select *Password* and enter the user's assigned password.
  - Select *Match user on LDAP server*, *Match user on RADIUS server*, or *Match user on TACACS+ server* and select the authentication server from the list. The authentication server must be already configured on the FortiGate unit.
4. Select *OK*.

### To create a user account - CLI

To create a user account called `user1` with the password `123_user`, enter:

```
config user local
  edit user1
    set type password
    set passwd "123_user"
    set status enable
  end
```

### Creating a user group

When clients connect using the L2TP-over-IPsec VPN, the FortiGate unit checks their credentials against the user group you specify for L2TP authentication. You need to create a firewall user group to use for this purpose.

#### To create a user group - web-based manager

1. Go to *User & Device > User > User Groups*, select *Create New*, and enter the following:

<b>Name</b>	Type or edit the user group name (for example, <code>L2TP_group</code> ).
<b>Type</b>	Select <i>Firewall</i> .
<b>Available Users/Groups</b>	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that can be added to the user group. To add a member to this list, select the name and then select the right arrow button.
<b>Members</b>	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that belong to the user group. To remove a member, select the name and then select the left arrow button.

2. Select *OK*.

#### To create a user group - CLI

To create the user group `L2TP_group` and add members `User_1`, `User_2`, and `User_3`, enter:

```
config user group
  edit L2TP_group
    set group-type firewall
    set member User_1 User_2 User_3
  end
```

### Configuring L2TP

You can only configure L2TP settings in the CLI. As well as enabling L2TP, you set the range of IP address values that are assigned to L2TP clients and specify the user group that can access the VPN. For example, to allow access to users in the `L2TP_group` and assign them addresses in the range `192.168.0.50` to `192.168.0.59`, enter:

```

config vpn l2tp
    set sip 192.168.0.50
    set eip 192.168.0.59
    set status enable
    set usrgroup "L2TP_group"
end

```

One of the security policies for the L2TP over IPsec VPN uses the client address range, so you need also need to create a firewall address for that range. For example,

```

config firewall address
    edit L2TPclients
        set type iprange
        set start-ip 192.168.0.50
        set end-ip 192.168.0.59
    end

```

Alternatively, you could define this range in the web-based manager.

## Configuring IPsec

The Microsoft VPN client uses IPsec for encryption. The configuration needed on the FortiGate unit is the same as for any other IPsec VPN with the following exceptions.

- Transport mode is used instead of tunnel mode.
- The encryption and authentication proposals must be compatible with the Microsoft client.

L2TP over IPsec is supported on the FortiGate unit using policy-based, not route-based configurations.

### Configuring phase 1 - web-based manager

1. Go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 1*.
2. Enter the following information and then select *OK*.

<b>Name</b>	Enter a name for this VPN, dialup_p1 for example.
<b>Remote Gateway</b>	Dialup User
<b>Local Interface</b>	Select the network interface that connects to the Internet. For example, port1.
<b>Mode</b>	Main (ID protection)
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key. This key must also be entered in the Microsoft VPN client.
<b>Advanced</b>	Select <i>Advanced</i> to enter the following information.
<b>Enable IPsec Interface Mode</b>	This must <b>not</b> be selected.
<b>P1 Proposal</b>	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
<b>DH Group</b>	2

<b>NAT Traversal</b>	Enable
<b>Dead Peer Detection</b>	Enable

### Configuring phase 1 - CLI

To create a phase 1 configuration called dialup\_p1 on a FortiGate unit that has port1 connected to the Internet, you would enter:

```
config vpn ipsec phase1
    edit dialup_p1
        set type dynamic
        set interface port1
        set mode main
        set psksecret *****
        set proposal aes256-md5 3des-sha1 aes192-sha1
        set dhgrp 2
        set nattraversal enable
        set dpd enable
    end
```

### Configuring phase 2 - web-based manager

1. Go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 2*.
2. Enter the following information and then select *OK*.

<b>Name</b>	Enter a name for this phase 2 configuration.
<b>Phase 1</b>	Select the name of the phase 1 configuration.
<b>Advanced</b>	Select <i>Advanced</i> to enter the following information.
<b>P2 Proposal</b>	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
<b>Enable replay detection</b>	Enable
<b>Enable perfect forward secrecy (PFS)</b>	Disable
<b>Keylife</b>	3600 seconds

3. Make this a transport-mode VPN. You must use the CLI to do this. If your phase 2 name is dialup\_p2, you would enter:

```
config vpn ipsec phase2
    edit dialup_p2
        set encapsulation transport-mode
    end
```

## Configuring phase 2 - CLI

To configure a phase 2 to work with your phase\_1 configuration, you would enter:

```
config vpn ipsec phase2
  edit dialup_p2
    set phase1name dialup_p1
    set proposal aes256-md5 3des-sha1 aes192-sha1
    set replay enable
    set pfs disable
    set keylifeseconds 3600
    set encapsulation transport-mode
  end
```

## Configuring security policies

The security policies required for L2TP over IPsec VPN are:

- an IPSEC policy, as you would create for any policy-based IPsec VPN
- a regular ACCEPT policy to allow traffic from the L2TP clients to access the protected network

### Configuring the IPSEC security policy - web-based manager

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.
3. Enter the following information and select *OK*:

<b>Local Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Local Protected Subnet</b>	All
<b>Outgoing VPN Interface</b>	Select the FortiGate unit's public interface.
<b>Remote Protected Subnet</b>	All
<b>VPN Tunnel</b>	Select <i>Use Existing</i> and select the name of the phase 1 configuration that you created. For example, dialup_p1. See <a href="#">“Configuring IPsec” on page 1789</a> .
<b>Allow traffic to be initiated from the remote site</b>	enable

### Configuring the IPSEC security policy - CLI

If your VPN tunnel (phase 1) is called dialup\_p1, your protected network is on port2, and your public interface is port1, you would enter:

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action ipsec
    set schedule always
    set service ANY
    set inbound enable
    set vpntunnel dialup_p1
  end
```

### Configuring the ACCEPT security policy - web-based manager

1. Go to *Policy > Policy > Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information and select *OK*:

<b>Incoming Interface</b>	Select the FortiGate unit's public interface.
<b>Source Address</b>	Select the firewall address that you defined for the L2TP clients.
<b>Outgoing Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Destination Address</b>	All
<b>Action</b>	ACCEPT

### Configuring the ACCEPT security policy - CLI

If your public interface is port1, your protected network is on port2, and L2TPclients is the address range that L2TP clients use, you would enter:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr L2TPclients
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  end
```

## Configuring the Windows PC

Configuration of the Windows PC for a VPN connection to the FortiGate unit consists of the following:

- In Network Connections, configure a Virtual Private Network connection to the FortiGate unit.
- Ensure that the IPSEC service is running.
- Ensure that IPsec has not been disabled for the VPN client. It may have been disabled to make the Microsoft VPN compatible with an earlier version of FortiOS.

The instructions in this section are based on Windows XP SP3. Other versions of Windows may vary slightly.

### To configure the network connection

1. Open *Network Connections*.

This is available through the Control Panel.

2. Double-click *New Connection Wizard* and *Select Next*.
3. Select *Connect to the network at my workplace*.
4. Select *Next*.
5. Select *Virtual Private Network connection* and select *Next*.
6. In the *Company Name* field, enter a name for the connection and select *Next*.
7. Select *Do not dial the initial connection* and then select *Next*.
8. Enter the public IP address or FQDN of the FortiGate unit and select *Next*.
9. Optionally, select *Add a shortcut to this connection to my desktop*.
10. Select *Finish*.

The *Connect* dialog opens on the desktop.

11. Select *Properties* and then select the *Security* tab.
12. Select *IPSec Settings*.
13. Select *Use pre-shared key for authentication*, enter the preshared key that you configured for your VPN, and select *OK*.
14. Select *OK*.

### To check that the IPSEC service is running

1. Open *Administrative Tools* through the Control Panel.
2. Double-click *Services*.
3. Look for IPSEC Services. Confirm that the *Startup Type* is *Automatic* and *Status* is set to *Started*. If needed, double-click *IPSEC Services* to change these settings.

### To check that IPsec has not been disabled

1. Select *Start > Run*.
2. Enter *regedit* and select *OK*.
3. Find the Registry key  
HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Services\RasMan\Parameters
4. If there is a *ProhibitIPSec* value, it must be set to 0.

## Troubleshooting

This section describes some checks and tools you can use to resolve issues with L2TP-over-IPsec VPNs.

This section includes:

- [Quick checks](#)
- [Mac OS X and L2TP](#)
- [Setting up logging](#)
- [Using the FortiGate unit debug commands](#)

### Quick checks

The table below is a list of common L2TP over IPsec VPN problems and the possible solutions.

Problem	What to check
IPsec tunnel does not come up.	<p>Check the logs to determine whether the failure is in Phase 1 or Phase 2.</p> <p>Check the settings, including encapsulation setting, which must be transport-mode.</p> <p>Check the user password.</p> <p>Confirm that the user is a member of the user group assigned to L2TP.</p> <p>On the Windows PC, check that the IPsec service is running and has not been disabled. See <a href="#">“Configuring the Windows PC” on page 1793</a>.</p>
Tunnel connects, but there is no communication.	<p>Did you create an ACCEPT security policy from the public network to the protected network for the L2TP clients? See <a href="#">“Configuring security policies” on page 1791</a>.</p>

### Mac OS X and L2TP

FortiOS allows L2TP connections with empty AVP host names and therefore Mac OS X L2TP connections can connect to the FortiGate.

Prior to FortiOS 4.0 MR3, FortiOS refused L2TP connections with empty AVP host names in compliance with RFC 2661 and RFC 3931.

### Setting up logging

L2TP logging must be enabled to record L2TP events. Alert email can be configured to report L2TP errors.

#### To configure FortiGate logging for L2TP over IPsec

1. Go to *Log & Report > Log Config > Log Settings*.
2. Select *Event Log*.
3. Select the *VPN activity event* check box.
4. Select *Apply*.

### To view FortiGate logs

1. Go to *Log & Report > Event Log > VPN*.
2. Select the *Log location* if required.
3. After each attempt to start the L2TP over IPsec VPN, select *Refresh* to view logged events.

## Using the FortiGate unit debug commands

### To view debug output for IKE and L2TP

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug application l2tp -1
diagnose debug enable
```
3. Attempt to use the VPN and note the debug output in the SSH or Telnet session.
4. Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

### To use the packet sniffer

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI command

```
diagnose sniffer packet any icmp 4
```
3. Attempt to use the VPN and note the debug output.
4. Enter **Ctrl-C** to end sniffer operation.

### Typical L2TP over IPsec session startup log entries - raw format

# GRE over IPsec (Cisco VPN)

This section describes how to configure a FortiGate VPN that is compatible with Cisco-style VPNs that use GRE in an IPsec tunnel.

The following topics are included in this section:

- [Overview](#)
- [Configuring the FortiGate unit](#)
- [Configuring the Cisco router](#)
- [Troubleshooting](#)

## Overview

Cisco products that include VPN support often use Generic Routing Encapsulation (GRE) protocol tunnel over IPsec encryption. This chapter describes how to configure a FortiGate unit to work with this type of Cisco VPN.

Cisco VPNs can use either transport mode or tunnel mode IPsec. Before FortiOS 4.0 MR2, the FortiGate unit was compatible only with tunnel mode IPsec.

**Figure 282:**Example FortiGate to Cisco GRE-over-IPsec VPN

In this example, users on LAN-1 are provided access to LAN-2.

# Configuring the FortiGate unit

There are several steps to the GRE-over-IPsec configuration:

- Enable overlapping subnets. This is needed because the IPsec and GRE tunnels will use the same addresses.
- Configure a route-based IPsec VPN on the external interface.
- Configure a GRE tunnel on the virtual IPsec interface. Set its local gateway and remote gateway addresses to match the local and remote gateways of the IPsec tunnel.
- Configure security policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Configure security policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.
- Configure a static route to direct traffic destined for the network behind the Cisco router into the GRE-over-IPsec tunnel.

## Enabling overlapping subnets

By default, each FortiGate unit network interface must be on a separate network. The configuration described in this chapter assigns an IPsec tunnel end point and the external interface to the same network. Enable subnet overlap as follows:

```
config system settings
    set allow-subnet-overlap enable
end
```

## Configuring the IPsec VPN

A route-based VPN is required. It must use encryption and authentication algorithms compatible with the Cisco equipment to which it connects. In this chapter, preshared key authentication is shown.

### To configure the IPsec VPN - web-based manager

1. Define the phase 1 configuration needed to establish a secure connection with the remote Cisco device. Enter these settings in particular:

<b>Name</b>	Enter a name to identify the VPN tunnel, tocsico for example. This is the name of the virtual IPsec interface. It appears in phase 2 configurations, security policies and the VPN monitor.
<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Enter the IP address of the Cisco device public interface. For example, 192.168.5.113.
<b>Local Interface</b>	Select the FortiGate unit's public interface. For example, 172.20.120.141.
<b>Mode</b>	Select <i>Main (ID Protection)</i> .
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key. It must match the preshared key on the Cisco device.

<b>Advanced</b>	Select the Advanced button to see the following settings.
<b>Enable IPsec Interface Mode</b>	Enable.
<b>P1 Proposal</b>	3DES-MD5  At least one proposal must match the settings on the Cisco unit.

For more information about these settings, see [“Auto Key phase 1 parameters” on page 1637](#).

2. Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. For compatibility with the Cisco router, Quick Mode Selectors must be entered, which includes specifying protocol 47, the GRE protocol. Enter these settings in particular:

<b>Name</b>	Enter a name to identify this phase 2 configuration.
<b>Phase 1</b>	Select the name of the phase 1 configuration that you defined in Step 1.
<b>Advanced</b>	Select <i>Advanced</i> to view the following fields.
<b>P2 Proposal</b>	3DES-MD5  At least one proposal must match the settings on the Cisco unit.
<b>Quick Mode Selector</b>	
<b>Source Address</b>	Enter the GRE local tunnel end IP address. For example 172.20.120.141.
<b>Source Port</b>	0
<b>Destination Address</b>	Enter the GRE remote tunnel end IP address. For example 192.168.5.113.
<b>Destination Port</b>	0
<b>Protocol</b>	47

For more information about these settings, see [“Phase 2 parameters” on page 1653](#).

3. If the Cisco device is configured to use transport mode IPsec, you need to use transport mode on the FortiGate VPN. You can configure this only in the CLI. In your phase 2 configuration, set encapsulation to transport-mode as follows:

```
config vpn phase2-interface
  edit to_cisco_p2
    set encapsulation transport-mode
  end
```

## To configure the IPsec VPN - CLI

```
config vpn ipsec phase1-interface
edit tocisco
set interface port1
set proposal 3des-sha1 aes128-sha1
set remote-gw 192.168.5.113
set psksecret xxxxxxxxxxxxxxxxx
end
config vpn ipsec phase2-interface
edit tocisco_p2
set phase1name "tocisco"
set proposal 3des-md5
set encapsulation tunnel-mode // if tunnel mode
set encapsulation transport-mode // if transport mode
set protocol 47
set src-addr-type ip
set dst-start-ip 192.168.5.113
set src-start-ip 172.20.120.141
end
```

## Adding IPsec tunnel end addresses

The Cisco configuration requires an address for its end of the IPsec tunnel. The addresses are set to match the GRE gateway addresses. Use the CLI to set the addresses, like this:

```
config system interface
edit tocisco
set ip 172.20.120.141 255.255.255.255
set remote-ip 192.168.5.113
end
```

## Configuring the GRE tunnel

The GRE tunnel runs between the virtual IPsec public interface on the FortiGate unit and the Cisco router. You must use the CLI to configure a GRE tunnel. In the example, you would enter:

```
config system gre-tunnel
edit gre1
set interface tocisco
set local-gw 172.20.120.141
set remote-gw 192.168.5.113
end
```

interface is the virtual IPsec interface, local-gw is the FortiGate unit public IP address, and remote-gw is the remote Cisco device public IP address

## Adding GRE tunnel end addresses

You will also need to add tunnel end addresses. The Cisco router configuration requires an address for its end of the GRE tunnel. Using the CLI, enter tunnel end addresses that are not used elsewhere on the FortiGate unit, like this:

```
config system interface
  edit gre1
    set ip 10.0.1.1 255.255.255.255
    set remote-ip 10.0.1.2
  end
```

## Configuring security policies

Two sets of security policies are required:

- policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.

### To configure security policies - web-based manager

1. Define an ACCEPT firewall security policy to permit communications between the protected network and the GRE tunnel:

<b>Incoming Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Select the GRE tunnel virtual interface you configured.
<b>Destination Address</b>	All
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Disable

2. To permit the remote client to initiate communication, you need to define a firewall address security policy for communication in that direction:

<b>Incoming Interface</b>	Select the GRE tunnel virtual interface you configured.
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Select the interface that connects to the private network behind this FortiGate unit.
<b>Destination Address</b>	All
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Disable

3. Define a pair of ACCEPT firewall address security policies to permit traffic to flow between the GRE virtual interface and the IPsec virtual interface:

<b>Incoming Interface</b>	Select the GRE virtual interface. See <a href="#">“Configuring the GRE tunnel” on page 1801</a> .
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Select the virtual IPsec interface you created. See <a href="#">“Configuring the IPsec VPN” on page 1799</a> .
<b>Destination Address</b>	All
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Disable

<b>Incoming Interface</b>	Select the virtual IPsec interface you created. See <a href="#">“Configuring the IPsec VPN” on page 1799</a> .
<b>Source Address</b>	All
<b>Outgoing Interface</b>	Select the GRE virtual interface. See <a href="#">“Configuring the GRE tunnel” on page 1801</a> .
<b>Destination Address</b>	All
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Disable

#### To configure security policies - CLI

```
config firewall policy
  edit 1                                // LAN to GRE tunnel
    set srcintf port2
    set dstintf gre1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 2                                // GRE tunnel to LAN
    set srcintf gre1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
```

```

edit 3                                // GRE tunnel to IPsec interface
    set srcintf "gre1"
    set dstintf "tocisco"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
next
edit 4                                // IPsec interface to GRE tunnel
    set srcintf "tocisco"
    set dstintf "gre1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
end

```

## Configuring routing

Traffic destined for the network behind the Cisco router must be routed to the GRE tunnel. To do this, create a static route

1. Go to *Router > Static > Static Routes* and select *Create New*.  
For low-end FortiGate units, go to *System > Network > Routing* and select *Create New*.
2. Enter the following information and select OK.

<b>Destination IP/Mask</b>	Enter the IP address and netmask for the network behind the Cisco router. For example 10.21.101.0 255.255.255.0.
<b>Device</b>	Select the GRE virtual interface.
<b>Distance (Advanced)</b>	Leave setting at default value.

In the CLI, using the example values, you would enter

```

config router static
    edit 0
        set device gre1
        set dst 10.21.101.0 255.255.255.0
    end

```

# Configuring the Cisco router

Using Cisco IOS, you would configure the Cisco router as follows, using the addresses from the example:

```
config ter
crypto ipsec transform-set myset esp-3des esp-md5-hmac
no mode
exit
no ip access-list extended tunnel
ip access-list extended tunnel
permit gre host 192.168.5.113 host 172.20.120.141
exit
interface Tunnell
ip address 10.0.1.2 255.255.255.0
tunnel source 192.168.5.113
tunnel destination 172.20.120.141
!
ip route 10.11.101.0 255.255.255.0 Tunnell
end
clea crypto sa
clea crypto isakmp
```

For transport mode, change no mode to mode transport.

This is only the portion of the Cisco router configuration that applies to the GRE-over-IPsec tunnel. For more information, refer to the Cisco documentation.

## Troubleshooting

This section describes some checks and tools you can use to resolve issues with the GRE-over-IPsec VPN.

### Quick checks

Here is a list of common problems and what to verify.

Problem	What to check
No communication with remote network.	Use the <code>execute ping</code> command to ping the Cisco device public interface.  Use the FortiGate VPN Monitor page to see whether the IPsec tunnel is up or can be brought up.

IPsec tunnel does not come up.	<p>Check the logs to determine whether the failure is in Phase 1 or Phase 2.</p> <p>Check that the encryption and authentication settings match those on the Cisco device.</p> <p>Check the encapsulation setting: tunnel-mode or transport-mode. Both devices must use the same mode.</p>
Tunnel connects, but there is no communication.	<p>Check the security policies. See <a href="#">“Configuring security policies” on page 1802</a>.</p> <p>Check routing. See <a href="#">“Configuring routing” on page 1804</a>.</p>

## Setting up logging

### To configure FortiGate logging for IPsec

1. Go to *Log & Report > Log Config > Log Settings*.
2. Select the *Event Logging*.
3. Select *VPN activity event*.
4. Select *Apply*.

### To view FortiGate logs

1. Go to *Log & Report > Event Log > VPN*.
2. Select the log storage type.
3. Select *Refresh* to view any logged events.

## Using diagnostic commands

There are some diagnostic commands that can provide useful information. When using diagnostic commands, it is best practice that you connect to the CLI using a terminal program, such as puTTY, that allows you to save output to a file. This will allow you to review the data later on at your own speed without worry about missed data as the diag output scrolls by.

### To use the packet sniffer

1. Enter the following CLI command:  

```
diag sniff packet any icmp 4
```
2. Ping an address on the network behind the FortiGate unit from the network behind the Cisco router.

The output will show packets coming in from the GRE interface going out of the interface that connects to the protected network (LAN) and vice versa. For example:

```
114.124303 gre1 in 10.0.1.2 -> 10.11.101.10: icmp: echo request
114.124367 port2 out 10.0.1.2 -> 10.11.101.10: icmp: echo request
114.124466 port2 in 10.11.101.10 -> 10.0.1.2: icmp: echo reply
114.124476 gre1 out 10.11.101.10 -> 10.0.1.2: icmp: echo reply
```

3. Enter CTRL-C to stop the sniffer.

### To view debug output for IKE

1. Enter the following CLI commands  

```
diagnose debug application ike -1
diagnose debug enable
```

2. Attempt to use the VPN or set up the VPN tunnel and note the debug output.
3. Enter CTRL-C to stop the debug output.
4. Enter the following command to reset debug settings to default:  
`diagnose debug reset`

# Protecting OSPF with IPsec

For enhanced security, OSPF dynamic routing can be carried over IPsec VPN links.

The following topics are included in this section:

- [Overview](#)
- [OSPF over IPsec configuration](#)
- [Creating a redundant configuration](#)

## Overview

This chapter shows an example of OSPF routing conducted over an IPsec tunnel between two FortiGate units. The network shown in [Figure 283](#) is a single OSPF area. FortiGate\_1 is an Area border router that advertises a static route to 10.22.10.0/24 in OSPF. FortiGate\_2 advertises its local LAN as an OSPF internal route.

**Figure 283:**OSPF over an IPsec VPN tunnel

The section [“OSPF over IPsec configuration”](#) describes the configuration with only one IPsec VPN tunnel, tunnel\_wan1. Then, the section [“Creating a redundant configuration”](#) on page 1814 describes how you can add a second tunnel to provide a redundant backup path. This is shown in [Figure 283](#) as VPN tunnel “tunnel\_wan2”.

Only the parts of the configuration concerned with creating the IPsec tunnel and integrating it into the OSPF network are described. It is assumed that security policies are already in place to allow traffic to flow between the interfaces on each FortiGate unit.

# OSPF over IPsec configuration

There are several steps to the OSPF-over-IPsec configuration:

- Configure a route-based IPsec VPN on an external interface. It will connect to a corresponding interface on the other FortiGate unit. Define the two tunnel-end addresses.
- Configure a static route to the other FortiGate unit.
- Configure the tunnel network as part of the OSPF network and define the virtual IPsec interface as an OSPF interface.

This section describes the configuration with only one VPN, tunnel\_wan1. The other VPN is added in the section [“Creating a redundant configuration” on page 1814](#).

## Configuring the IPsec VPN

A route-based VPN is required. In this chapter, preshared key authentication is shown. Certificate authentication is also possible. Both FortiGate units need this configuration.

### To configure Phase 1

- 1 Define the phase 1 configuration needed to establish a secure connection with the other FortiGate unit. For more information, see [“Auto Key phase 1 parameters” on page 1637](#). Enter these settings in particular:

<b>Name</b>	Enter a name to identify the VPN tunnel, tunnel_wan1 for example. This becomes the name of the virtual IPsec interface.
<b>Remote Gateway</b>	Select <i>Static IP Address</i> .
<b>IP Address</b>	Enter the IP address of the other FortiGate unit’s public (Port 2) interface.
<b>Local Interface</b>	Select this FortiGate unit’s public (Port 2) interface.
<b>Mode</b>	Select <i>Main (ID Protection)</i> .
<b>Authentication Method</b>	Preshared Key
<b>Pre-shared Key</b>	Enter the preshared key. It must match the preshared key on the other FortiGate unit.
<b>Advanced</b>	Select <i>Advanced</i> .
<b>Enable IPsec Interface Mode</b>	Enable

### To assign the tunnel end IP addresses

1. Go to *System > Network > Interfaces*, select the virtual IPsec interface that you just created on Port 2 and select *Edit*.
2. In the *IP* and *Remote IP* fields, enter the following tunnel end addresses:

	<b>FortiGate_1</b>	<b>FortiGate_2</b>
<b>IP</b>	10.1.1.1	10.1.1.2
<b>Remote_IP</b>	10.1.1.2	10.1.1.1

These addresses are from a network that is not used for anything else.

## To configure Phase 2

1. Enter a name to identify this phase 2 configuration, `twan1_p2`, for example.
2. Select the name of the phase 1 configuration that you defined in Step 1, `tunnel_wan1` for example.

## Configuring static routing

You need to define the route for traffic leaving the external interface.

1. Go to *Router > Static > Static Routes*, select *Create New*.
2. For low-end FortiGate units, go to *System > Network > Routing* and select *Create New*.
3. Enter the following information.

<b>Destination IP/Mask</b>	Leave as 0.0.0.0 0.0.0.0.
<b>Device</b>	Select the external interface.
<b>Gateway</b>	Enter the IP address of the next hop router.

## Configuring OSPF

This section does not attempt to explain OSPF router configuration. It focusses on the integration of the IPsec tunnel into the OSPF network. This is accomplished by assigning the tunnel as an OSPF interface, creating an OSPF route to the other FortiGate unit.

This configuration uses loopback interfaces to ease OSPF troubleshooting. The OSPF router ID is set to the loopback interface address. The loopback interface ensures the router is always up. Even though technically the router ID doesn't have to match a valid IP address on the FortiGate unit, having an IP that matches the router ID makes troubleshooting a lot easier.

The two FortiGate units have slightly different configurations. FortiGate\_1 is an AS border router that advertises its static default route. FortiGate\_2 advertises its local LAN as an OSPF internal route.

Setting the router ID for each FortiGate unit to the lowest possible value is useful if you want the FortiGate units to be the designated router (DR) for their respective ASes. This is the router that broadcasts the updates for the AS.

Leaving the IP address on the OSPF interface at 0.0.0.0 indicates that all potential routes will be advertised, and it will not be limited to any specific subnet. For example if this IP address was 10.1.0.0, then only routes that match that subnet will be advertised through this interface in OSPF.

### FortiGate\_1 OSPF configuration

When configuring FortiGate\_1 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

## To create the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.1, you would enter:

```
config system interface
edit lback1
set vdom root
set ip 10.0.0.1 255.255.255.255
set type loopback
end
```

The loopback addresses and corresponding router IDs on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

## To configure OSPF area, networks, and interfaces - web-based manager

1. On FortiGate\_1, go to *Router > Dynamic > OSPF*.

For low end FortiGate units, you first need to enable *Dynamic Routing* by going to *System > Admin > Settings*.

2. Enter the following information to define the router, area, and interface information.

<b>Router ID</b>	Enter 10.0.0.1. Select <i>Apply</i> before entering the remaining information.
<b>Advanced Options</b>	
<b>Redistribute</b>	Select the <i>Connected</i> and <i>Static</i> check boxes. Use their default metric values.
<b>Areas</b>	Select <i>Create New</i> , enter the <i>Area</i> and <i>Type</i> and then select <i>OK</i> .
<b>Area</b>	0.0.0.0
<b>Type</b>	Regular
<b>Interfaces</b>	Enter a name for the OSPF interface, ospf_wan1 for example.
<b>Name</b>	
<b>Interface</b>	Select the virtual IPsec interface, tunnel_wan1.
<b>IP</b>	0.0.0.0

3. For *Networks*, select *Create New*.
4. Enter the *IP/Netmask* of 10.1.1.0/255.255.255.0 and an *Area* of 0.0.0.0.
5. For *Networks*, select *Create New*.
6. Enter the *IP/Netmask* of 10.0.0.1/255.255.255.0 and an *Area* of 0.0.0.0.
7. Select *Apply*.

## To configure OSPF area and interfaces - CLI

Your loopback interface is 10.0.0.1, your tunnel ends are on the 10.1.1.0/24 network, and your virtual IPsec interface is named `tunnel_wan1`. Enter the following CLI commands:

```
config router ospf
  set router-id 10.0.0.1
  config area
    edit 0.0.0.0
  end
  config network
    edit 4
      set prefix 10.1.1.0 255.255.255.0
    next
    edit 2
      set prefix 10.0.0.1 255.255.255.255
    end
  config ospf-interface
    edit ospf_wan1
      set cost 10
      set interface tunnel_wan1
      set network-type point-to-point
    end
  config redistribute connected
    set status enable
  end
  config redistribute static
    set status enable
  end
end
```

## FortiGate\_2 OSPF configuration

When configuring FortiGate\_2 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

Configuring FortiGate\_2 differs from FortiGate\_1 in that three interfaces are defined instead of two. The third interface is the local LAN that will be advertised into OSPF.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

### To create the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.2, you would enter:

```
config system interface
  edit lback1
    set vdom root
    set ip 10.0.0.2 255.255.255.255
    set type loopback
  end
```

The loopback addresses on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

## To configure OSPF area and interfaces - web-based manager

1. On FortiGate\_2, go to *Router > Dynamic > OSPF*.

For low end FortiGate units, you first need to enable *Dynamic Routing* by going to *System > Admin > Settings*.

2. Complete the following.

<b>Router ID</b>	10.0.0.2
<b>Areas</b>	Select <i>Create New</i> , enter the <i>Area</i> and <i>Type</i> and then select <i>OK</i> .
<b>Area</b>	0.0.0.0
<b>Type</b>	Regular
<b>Interfaces</b>	
<b>Name</b>	Enter a name for the OSPF interface, ospf_wan1 for example.
<b>Interface</b>	Select the virtual IPsec interface, tunnel_wan1.
<b>IP</b>	0.0.0.0

3. For *Networks*, select *Create New*.

4. Enter the following information for the loopback interface:

<b>IP/Netmask</b>	10.0.0.2/255.255.255.255
<b>Area</b>	0.0.0.0

5. For *Networks*, select *Create New*.

6. Enter the following information for the tunnel interface:

<b>IP/Netmask</b>	10.1.1.0/255.255.255.255
<b>Area</b>	0.0.0.0

7. For *Networks*, select *Create New*.

8. Enter the following information for the local LAN interface:

<b>IP/Netmask</b>	10.31.101.0/255.255.255.255
<b>Area</b>	0.0.0.0

9. Select *Apply*.

## To configure OSPF area and interfaces - CLI

If for example, your loopback interface is 10.0.0.2, your tunnel ends are on the 10.1.1.0/24 network, your local LAN is 10.31.101.0/24, and your virtual IPsec interface is named tunnel\_wan1, you would enter:

```
config router ospf
  set router-id 10.0.0.2
  config area
    edit 0.0.0.0
  end
  config network
    edit 1
      set prefix 10.1.1.0 255.255.255.0
    next
    edit 2
      set prefix 10.31.101.0 255.255.255.0
    next
    edit 2
      set prefix 10.0.0.2 255.255.255.255
    end
  config ospf-interface
    edit ospf_wan1
      set interface tunnel_wan1
      set network-type point-to-point
    end
  end
end
```

## Creating a redundant configuration

You can improve the reliability of the OSPF over IPsec configuration described in the previous section by adding a second IPsec tunnel to use if the default one goes down. Redundancy in this case is not controlled by the IPsec VPN configuration but by the OSPF routing protocol.

To do this you:

- Create a second route-based IPsec tunnel on a different interface and define tunnel end addresses for it.
- Add the tunnel network as part of the OSPF network and define the virtual IPsec interface as an additional OSPF interface.
- Set the OSPF cost for the added OSPF interface to be significantly higher than the cost of the default route.

## Adding the second IPsec tunnel

The configuration is the same as in [“Configuring the IPsec VPN” on page 1809](#), but the interface and addresses will be different. Ideally, the network interface you use is connected to a different Internet service provider for added redundancy.

When adding the second tunnel to the OSPF network, choose another unused subnet for the tunnel ends, 10.1.2.1 and 10.1.2.2 for example.

## Adding the OSPF interface

OSPF uses the metric called cost when determining the best route, with lower costs being preferred. Up to now in this example, only the default cost of 10 has been used. Cost can be set only in the CLI.

The new IPsec tunnel will have its OSPF cost set higher than that of the default tunnel to ensure that it is only used if the first tunnel goes down. The new tunnel could be set to a cost of 200 compared to the default cost is 10. Such a large difference in cost will ensure this new tunnel will only be used as a last resort.

If the new tunnel is called `tunnel_wan2`, you would enter the following on both FortiGate units:

```
config router ospf
  config ospf-interface
    edit ospf_wan2
      set cost 200
      set interface tunnel_wan2
      set network-type point-to-point
    end
  end
end
```

# Hardware offloading and acceleration

FortiGate units incorporate proprietary FortiASIC NPx network processors that can provide accelerated processing for IPsec VPN traffic. This section describes how to configure offloading and acceleration.

The following topics are included in this section:

- [Overview](#)
- [IPsec offloading configuration examples](#)

## Overview

Fortinet's NPx network processors contain features to improve IPsec tunnel performance. For example, network processors can encrypt and decrypt packets, offloading cryptographic work from the FortiGate unit's main processing resources.

On FortiGate units with the appropriate hardware, you can configure offloading of both IPsec sessions and HMAC checking.

## IPsec session offloading requirements

Sessions must be fast path ready. Fast path ready session requirements are:

- Layer 2 type/length must be 0x0800 (IEEE 802.1q VLAN specification is supported); link aggregation between any network interfaces sharing the same network processor(s) may be used (IEEE 802.3ad specification is supported)
- Layer 3 protocol must be IPv4
- Layer 4 protocol must be UDP, TCP or ICMP
- Layer 3 / Layer 4 header or content modification must not require a session helper (for example, SNAT, DNAT, and TTL reduction are supported, but application layer content modification is not supported)
- FortiGate unit security policy must not require antivirus or IPS inspection, although hardware accelerated anomaly checks are acceptable.
- The session must not use an aggregated link or require QoS, including rate limits and bandwidth guarantees (NP1 processor only).
- Ingress and egress network interfaces are both attached to the same network processor(s)
- In Phase I configuration, Local Gateway IP must be specified as an IP address of a network interface attached to a network processor
- In Phase II configuration:
  - encryption algorithm must be DES, 3DES, AES-128, AES-192, AES-256, or null (for NP1 processor, only 3DES is supported)
  - authentication must be MD5, SHA1, or null (for NP1 processor, only MD5 is supported)
  - if replay detection is enabled, encryption and decryption options must be enabled in the CLI (see [“IPsec encryption offloading”](#), below)

If the IPsec session meets the above requirements, the FortiGate unit sends the IPsec security association (SA) and configured processing actions to the network processors.

## Packet offloading requirements

In addition to the session requirements, the packets themselves must meet fast-path requirements:

- Incoming packets must not be fragmented.
- Outgoing packets must be 385 bytes or larger after any fragmentation. This means the configured MTU (Maximum Transmission Unit) for the network processors' interfaces must have an MTU of 385 bytes or larger.

If packet offloading requirements are not met, an individual packet will use the FortiGate unit main processing resources, regardless of whether other packets in the session are offloaded to the specialized network processors.

## IPsec encryption offloading

Network processing unit (NPU) settings configure offloading behavior for IPsec VPNs. Configured behavior applies to all network processors contained by the FortiGate unit itself or any installed AMC modules.

If replay detection is not enabled (IPsec Phase 2 settings), encryption is always offloaded. NPU offloading is supported when the local gateway is a loopback interface.

### To enable offloading of encryption even when replay detection is enabled

```
config system npu
    set enc-offload-antireplay enable
    set offload-ipsec-host enable
end
```

### To enable offloading of decryption even when replay detection is enabled

```
config system npu
    set dec-offload-antireplay enable
end
```

## HMAC check offloading

The Hash-based Message Authentication Code (HMAC) check can also be offloaded to hardware. SHA-256, SHA-384, or SHA-512 cannot be off-loaded to hardware, and must be processed using only software resources.

### To enable HMAC check offloading

```
configure system global
    set ipsec-hmac-offload (enable|disable)
end
```

## IPsec offloading configuration examples

The following examples configure two FortiASIC NPx network processor accelerated VPNs, one route-based, the other policy based. In both cases, the network topology is as shown in [Figure 284](#).

**Figure 284:**Hardware accelerated IPsec VPN topology

## Accelerated route-based VPN configuration

This example uses the accelerated ports on FortiGate-ASM-FB4 modules in each FortiGate unit. These accelerated ports on the modules are paired interfaces that have their own network processor (NPU) to offload work from the FortiGate unit CPU. Beyond this fact, the example is normal VPN example.

Configuring the FortiGate units require the same basic steps:

- Configure VPN Phase 1
- Configure VPN Phase 2
- Create security policies to allow traffic to flow
- Create a static route to allow traffic to flow

When both FortiGates are have the VPN tunnel configured, test to ensure it is working properly.

### To configure FortiGate\_1

1. Go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 1*.
2. Configure Phase 1 settings (name *FGT\_1\_IPsec*), plus
  - Select *Advanced*.
  - Select *Enable IPsec Interface Mode*.
  - In *Local Gateway IP*, select *Specify* and enter the VPN IP address 3.3.3.1, which is the IP address of FortiGate\_1's FortiGate-ASM-FB4 module on port 2.
3. Select *OK*.
4. Select *Create Phase 2* and configure Phase 2 settings, including
  - Select *Enable replay detection*.
  - set `enc-offload-antireplay` to `enable` using the `config system npu` CLI command.
5. Go to *Policy > Policy > Policy*.
6. Configure two firewall address policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.
7. Go to *Router > Static > Static Routes*.  
For low-end FortiGate units, go to *System > Network > Routing*.

8. Configure a static route to route traffic destined for FortiGate\_2's protected network to the virtual IPsec interface, FGT\_1\_IPsec.

**To add the static route from the CLI:**

```
config router static
  edit 2
    set device "FGT_1_IPsec"
    set dst 2.2.2.0 255.255.255.0
  end
```

**To configure FortiGate\_2**

1. Go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 1*.
2. Configure Phase 1 settings (name FGT\_2\_IPsec), plus
  - Select *Advanced*.
  - Select *Enable IPsec Interface Mode*.
  - In *Local Gateway IP*, select *Specify* and enter the VPN IP address 3.3.3.2, which is the IP address of FortiGate\_2's FortiGate-ASM-FB4 module on port 2.
3. Select *OK*.
4. Select *Create Phase 2* and configure Phase 2 settings, including
  - Select *Enable replay detection*.
  - set `enc-offload-antireplay` to enable using the `config system npu` CLI command.
5. Go to *Policy > Policy > Policy*.
6. Configure two firewall address policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.
7. Go to *Router > Static > Static Routes*.
8. Configure a static route to route traffic destined for FortiGate\_1's protected network to the virtual IPsec interface, FGT\_2\_IPsec.

**To add the static route from the CLI:**

```
config router static
  edit 2
    set device "FGT_2_IPsec"
    set dst 1.1.1.0 255.255.255.0
  end
```

**To test the VPN**

1. Activate the IPsec tunnel by sending traffic between the two protected networks.
2. To verify tunnel activation, go to *VPN > Monitor > IPsec Monitor*.

## Accelerated policy-based VPN configuration

### To configure FortiGate\_1

1. Go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 1*.
2. Configure Phase 1 settings (name FGT\_1\_IPsec), plus
  - Select *Advanced*.
  - Ensure that the *Enable IPsec Interface Mode* check box is not selected.
  - In *Local Gateway IP*, select *Specify* and enter the VPN IP address 3.3.3.1, which is the IP address of FortiGate\_1's FortiGate-ASM-FB4 module on port 2.
3. Select *OK*.
4. Select *Create Phase 2* and configure Phase 2 settings, including
  - Select *Enable replay detection*.
  - `set enc-offload-antireplay to enable` using the `config system npu CLI` command.
5. Go to *Policy > Policy > Policy*.
6. Configure an IPsec VPN policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-ASM-FB4 module ports 1 and 2.
7. Go to *Router > Static > Static Routes*.  
For low-end FortiGate units, go to *System > Network > Routing*.
8. Configure a static route to route traffic destined for FortiGate\_2's protected network to FortiGate\_2's VPN gateway, 3.3.3.2, through the FortiGate-ASM-FB4 module's port 2 (device).

### To add the static route from the CLI:

```
config router static
  edit 0
    set device "AMC-SW1/2"
    set dst 2.2.2.0 255.255.255.0
    set gateway 3.3.3.1
  end
```

### To configure FortiGate\_2

1. Go to *VPN > IPsec > Auto Key (IKE)* and select *Create Phase 1*.
2. Configure Phase 1 settings (name FGT\_2\_IPsec), plus
  - Select *Advanced*.
  - Select *Enable IPsec Interface Mode*.
  - In *Local Gateway IP*, select *Specify* and enter the VPN IP address 3.3.3.2, which is the IP address of FortiGate\_2's FortiGate-ASM-FB4 module on port 2.
3. Select *OK*.
4. Select *Create Phase 2* and configure Phase 2 settings, including
  - Select *Enable replay detection*.
  - `set enc-offload-antireplay to enable` using the `config system npu CLI` command.
5. Go to *Policy > Policy > Policy*.
6. Configure an IPsec VPN policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-ASM-FB4 module ports 1 and 2.

7. Go to *Router > Static > Static Routes*.

For low-end FortiGate units, go to *System > Network > Routing*.

8. Configure a static route to route traffic destined for FortiGate\_1's protected network to FortiGate\_2's VPN gateway, 3.3.3.2, through the FortiGate-ASM-FB4 module's port 2 (device).

**To add the static route from the CLI:**

```
config router static
edit 0
    set device "AMC-SW1/2"
    set dst 1.1.1.0 255.255.255.0
    set gateway 3.3.3.2
end
```

**To test the VPN**

1. Activate the IPsec tunnel by sending traffic between the two protected networks.
2. To verify tunnel activation, go to *VPN > Monitor > IPsec Monitor*.

# Monitoring and troubleshooting

This section provides some general maintenance and monitoring procedures for VPNs.

The following topics are included in this section:

- [Monitoring VPN connections](#)
- [Testing VPN connections](#)
- [Testing VPN connections](#)
- [Logging VPN events](#)
- [VPN troubleshooting tips](#)

## Monitoring VPN connections

You can use the monitor to view activity on IPsec VPN tunnels and to start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels.

### Monitoring connections to remote peers

The list of tunnels provides information about VPN connections to remote peers that have static IP addresses or domain names. You can use this list to view status and IP addressing information for each tunnel configuration. You can also start and stop individual tunnels from the list.

To view the list of static-IP and dynamic-DNS tunnels go to *VPN > Monitor > IPsec Monitor*.

### Monitoring dialup IPsec connections

The list of dialup tunnels provides information about the status of tunnels that have been established for dialup clients. The list displays the IP addresses of dialup clients and the names of all active tunnels. The number of tunnels shown in the list can change as dialup clients connect and disconnect.

To view the list of dialup tunnels go to *VPN > Monitor > IPsec Monitor*.

If you take down an active tunnel while a dialup client such as FortiClient is still connected, FortiClient will continue to show the tunnel connected and idle. The dialup client must disconnect before another tunnel can be initiated.

The list of dialup tunnels displays the following statistics:

- The Name column displays the name of the tunnel.
- The meaning of the value in the Remote gateway column changes, depending on the configuration of the network at the far end:
  - When a FortiClient dialup client establishes a tunnel, the Remote gateway column displays either the public IP address and UDP port of the remote host device (on which the FortiClient Endpoint Security application is installed), or if a NAT device exists in front

of the remote host, the Remote gateway column displays the public IP address and UDP port of the remote host.

- When a FortiGate dialup client establishes a tunnel, the Remote gateway column displays the public IP address and UDP port of the FortiGate dialup client.
- The Username column displays the peer ID, certificate name, or XAuth user name of the dialup client (if a peer ID, certificate name, or XAuth user name was assigned to the dialup client for authentication purposes).
- The Timeout column displays the time before the next key exchange. The time is calculated by subtracting the time elapsed since the last key exchange from the keylife.
- The Proxy ID Source column displays the IP addresses of the hosts, servers, or private networks behind the FortiGate unit. A network range may be displayed if the source address in the security encryption policy was expressed as a range of IP addresses.
- The meaning of the value in the Proxy ID Destination column changes, depending on the configuration of the network at the far end:
  - When a FortiClient dialup client establishes a tunnel:
    - If VIP addresses are not used and the remote host connects to the Internet directly, the Proxy ID Destination field displays the public IP address of the Network Interface Card (NIC) in the remote host.
    - If VIP addresses are not used and the remote host is behind a NAT device, the Proxy ID Destination field displays the private IP address of the NIC in the remote host.
    - If VIP addresses were configured (manually or through FortiGate DHCP relay), the Proxy ID Destination field displays either the VIP address belonging to a FortiClient dialup client, or a subnet address from which VIP addresses were assigned.
  - When a FortiGate dialup client establishes a tunnel, the Proxy ID Destination field displays the IP address of the remote private network.

## Testing VPN connections

A VPN connection has multiple stages that can be confirmed to ensure the connection is working properly. It is easiest to see if the final stage is successful first since if it is successful the other stages will be working properly. Otherwise, you will need to work back through the stages to see where the problem is located.

When a VPN connection is properly established, traffic will flow from one end to the other as if both ends were physically in the same place. If you can determine the connection is working properly then any problems are likely problems with your applications.

If the connection is not working properly, you can move on to [“Troubleshooting VPN connections” on page 1824](#) to determine the exact problem.

### LAN interface connection

To confirm whether a VPN connection over LAN interfaces has been configured correctly, issue a ping or traceroute command on the network behind the FortiGate unit to test the connection to a computer on the remote network. If the connection is properly configured, a VPN tunnel will be established automatically when the first data packet destined for the remote network is intercepted by the FortiGate unit.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel. You can confirm this by going to *VPN > Monitor > IPsec Monitor* where you will be able to see your connection. A green arrow means the tunnel is up and currently processing traffic. A red arrow means the tunnel is not processing traffic, and this VPN connection has a problem.

If the connection has problems, see [“Troubleshooting VPN connections” on page 1824](#).

## Dialup connection

A dialup VPN connection has additional steps. To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel, or dialup client. As with the LAN connection, confirm the VPN tunnel is established by checking *VPN > Monitor > IPsec Monitor*.

## Troubleshooting VPN connections

If you have determined that your VPN connection is not working properly through [“Testing VPN connections” on page 1823](#), the next step is to verify that you have a phase2 connection.

If traffic is not passing through the FortiGate unit as you expect, ensure the traffic does not contain IPcomp packets (IP protocol 108, RFC 3173). FortiGate units do not allow IPcomp packets, they compress packet payload, preventing it from being scanned.

Testing phase 1 and 2 connections is a bit more difficult than testing the working VPN. This is because they require diagnose CLI commands. These commands are typically used by Fortinet customer support to discover more information about your FortiGate unit and its current configuration.

Before you start troubleshooting you need to:

- configure FortiGate units on both ends for interface VPN
- record the information in your VPN phase 1 and phase 2 configurations - for our example here the remote IP address is 10.11.101.10 and the names of the phases are Phase1 and Phase2
- install a telnet or SSH client such as putty that allows logging of output
- ensure that the admin interface supports your chosen connection protocol so you can connect to your FortiGate unit admin interface.
- For this example, default values were used unless stated otherwise.

### To get diagnose information for the VPN connection - CLI

1. Log into the CLI as admin with the output being logged to a file.
2. Stop any diagnose debug sessions that are currently running with the CLI command  
`diagnose debug disable`
3. Clear any existing log-filters by running  
`diagnose vpn ike log-filter clear`
4. Set the log-filter to the IP address of the remote computer (10.11.101.10). This filters out all VPN connections except ones to the IP address we are concerned with. The command is  
`diagnose vpn ike log-filter dst-addr4 10.11.101.10.`
5. Set up the commands to output the VPN handshaking. The commands are:  
`diagnose debug app ike 255`  
`diagnose debug enable`

6. Have the remote FortiGate initiate the VPN connection in the web-based manager by going to *VPN > Monitor* and selecting *Bring up*.

This makes the remote FortiGate the initiator and the local FortiGate becomes the responder. Establishing the connection in this manner means the local FortiGate will have its configuration information as well as the information the remote computer sends. Having both sets of information locally makes it easier to troubleshoot your VPN connection.

7. Watch the screen for output, and after roughly 15 seconds enter the following CLI command to stop the output.

```
diagnose debug disable
```

8. If needed, save the log file of this output to a file on your local computer. Saving the output to a file can make it easier to search for a particular phrase, and is useful for comparisons.

### To troubleshoot a phase1 VPN connection

Using the output from [“To get diagnose information for the VPN connection - CLI” on page 1824](#), search for the word `proposal` in the output. It may occur once indicating a successful connection, or it will occur two or more times for an unsuccessful connection — there will be one proposal listed for each end of the tunnel and each possible combination in their settings. For example if 10.11.101.10 selected both DH Group 1 and 5, that would be at least 2 proposals set.

A successful negotiation proposal will look similar to

```
IPsec SA connect 26 10.12.101.10->10.11.101.10:500
config found
created connection: 0x2f55860 26 10.12.101.10->10.11.101.10:500
IPsec SA connect 26 10.12.101.10->10.11.101.10:500 negotiating
no suitable ISAKMP SA, queuing quick-mode request and initiating
    ISAKMP SA negotiation
initiator: main mode is sending 1st message...
cookie 3db6afe559e3df0f/0000000000000000
out [encryption]
sent IKE msg (ident-ilsend): 10.12.101.10:500->10.11.101.10:500,
    len=264, id=3db6afe559e3df0f/0000000000000000
diaike 0: comes 10.12.101.1:500->10.11.101.1:500,ifindex=26....
```

Note the phrase “initiator: main mode is sending 1st message...” which shows you the handshake between the ends of the tunnel is in progress. Initiator shows the remote unit is sending the first message.

## Logging VPN events

You can configure the FortiGate unit to log VPN events. For IPsec VPNs, phase 1 and phase 2 authentication and encryption events are logged. For information about how to interpret log messages, see the [FortiGate Log Message Reference](#).

### To log VPN events

1. Go to *Log & Report > Log Config > Log Settings*.
2. Verify that the *VPN activity event* option is selected.
3. Select *Apply*.

### To view event logs

1. Go to *Log & Report > Event Log > VPN*.
2. Select the *Log location*.

## VPN troubleshooting tips

More in-depth VPN troubleshooting can be found in the [Troubleshooting guide handbook chapter](#).

### The VPN proposal is not connecting

One side may attempt to initiate the VPN tunnel unsuccessful. There are a number of potential reasons for this problem.

### Attempting hardware offloading beyond SHA1

If you are trying to off-load VPN processing to a network processing unit (NPU), remember that only SHA1 authentication is supported. For high levels of authentication such as SHA256, SHA384, and SHA512 hardware offloading is not an option — all VPN processing must be done in software.

### Check Phase 1 proposal settings

Ensure that both sides have at least one Phase 1 proposal in common. Otherwise they will not connect. If there are many proposals in the list, this will slow down the negotiating of Phase 1. If its too slow, the connection may timeout before completing. If this happens, try removing some of the unused proposals.

NPU offloading is supported when the local gateway is a loopback interface.

### Check your routing

If routing is not properly configured with an entry for the remote end of the VPN tunnel, traffic will not flow properly. You may need static routes on both ends of the tunnel. If routing is the problem, the proposal will likely setup properly but no traffic will flow.

### Try enabling XAuth

If one end of an attempted VPN tunnel is using XAuth and the other end is not, the connection attempt will fail. The log messages for the attempted connection will not mention XAuth is the reason, but when connections are failing it is a good idea to ensure both ends have the same XAuth settings. If you do not know the other end's settings enable or disable XAuth on your end to see if that is the problem.

## General troubleshooting tips

Most connection failures are due to a configuration mismatch between the FortiGate unit and the remote peer. In general, begin troubleshooting an IPsec VPN connection failure as follows:

1. Ping the remote network or client to verify whether the connection is up. See [“Testing VPN connections” on page 1823](#).
2. Traceroute the remote network or client. If DNS is working, you can use domain names. Otherwise use IP addresses.
3. Check the routing behind the dialup client. Routing problems may be affecting DHCP. If this appears to be the case, configure a DHCP relay service to enable DHCP requests to be relayed to a DHCP server on or behind the FortiGate server.

4. Verify the configuration of the FortiGate unit and the remote peer. Check the following IPsec parameters:
  - The mode setting for ID protection (main or aggressive) on both VPN peers must be identical.
  - The authentication method (preshared keys or certificates) used by the client must be supported on the FortiGate unit and configured properly.
  - If preshared keys are being used for authentication purposes, both VPN peers must have identical preshared keys.
  - The remote client must have at least one set of phase 1 encryption, authentication, and Diffie-Hellman settings that match corresponding settings on the FortiGate unit.
  - Both VPN peers must have the same NAT traversal setting (enabled or disabled).
  - The remote client must have at least one set of phase 2 encryption and authentication algorithm settings that match the corresponding settings on the FortiGate unit.
  - If you are using manual keys to establish a tunnel, the *Remote SPI* setting on the FortiGate unit must be identical to the *Local SPI* setting on the remote peer, and vice versa.
5. To correct the problem, see the following table.

**Table 75: VPN trouble-shooting tips**

Configuration problem	Correction
<b>Mode settings do not match.</b>	Select complementary mode settings. See <a href="#">“Choosing main mode or aggressive mode” on page 1638</a> .
<b>Peer ID or certificate name of the remote peer or dialup client is not recognized by FortiGate VPN server.</b>	Check Phase 1 configuration. Depending on the Remote Gateway and Authentication Method settings, you have a choice of options to authenticate FortiGate dialup clients or VPN peers by ID or certificate name (see <a href="#">“Authenticating remote peers and clients” on page 1642</a> ).  If you are configuring authentication parameters for FortiClient dialup clients, refer to the <a href="#">Authenticating FortiClient Dialup Clients Technical Note</a> .
<b>Preshared keys do not match.</b>	Reenter the preshared key. See <a href="#">“Authenticating remote peers and clients” on page 1642</a> .
<b>Phase 1 or phase 2 key exchange proposals are mismatched.</b>	Make sure that both VPN peers have at least one set of proposals in common for each phase. See <a href="#">“Defining IKE negotiation parameters” on page 1646</a> and <a href="#">“Configure the phase 2 parameters” on page 1655</a> .
<b>NAT traversal settings are mismatched.</b>	Select or clear both options as required. See <a href="#">“NAT traversal” on page 1649</a> and <a href="#">“NAT keepalive frequency” on page 1650</a> .
<b>SPI settings for manual key tunnels are mismatched.</b>	Enter complementary SPI settings. See <a href="#">“Manual-key configurations” on page 1770</a> .

## A word about NAT devices

When a device with NAT capabilities is located between two VPN peers or a VPN peer and a dialup client, that device must be NAT traversal (NAT-T) compatible for encrypted traffic to pass through the NAT device. For more information, see [“NAT traversal” on page 1649](#).

# IPv6 for FortiOS 5.0

The origins of Internet Protocol Version 6 (IPv6) date back to December 1998 with the publication of [RFC 2460](#), which describes IPv6 as the successor to IPv4, the standard communications protocol still in use by the majority of users today. This transition away from IPv4 was a direct response to the foreseeable exhaustion of 32-bit IPv4 addresses, which are virtually all but assigned—all 4.3 billion.

IPv4 uses 32-bit addresses, which means that there is a theoretical address limit of  $2^{32}$ . The IPv6 address scheme is based on a 128-bit address, resulting in a theoretical address limit of  $2^{128}$ .

## Possible addresses:

- IPv4 = Roughly 4.3 billion
- IPv6 = Over 340 undecillion (340 followed by 36 digits)

Assuming a world population of approximately 8 billion people, IPv6 would allow for each individual to have approximately 42,535,295,865,117,200,000,000,000,000 devices with an IP address. That's 42 quintillion devices, so it's unlikely that we will ever need to worry about the availability of IPv6 addresses.

Aside from the difference of possible addresses, there is also the different formatting of the addresses. A computer would view an IPv4 address as a 32-bit string of binary digits made up of 1s and 0s, broken up into 4 octets of 8 digits separated by a period:

```
10101100.00010000.11111110.00000001
```

To make the number more user-friendly, we translate the address into decimal, again 4 octets separated by a period:

```
172.16.254.1
```

A computer would view an IPv6 address as a 128-bit string of binary digits made up of 1s and 0s, broken up into 8 octets of 16 digits separated by a colon:

```
0010000000000001:0000110110111:0000000000000000:00000000  
0000010:0000000000000000:0000000000000000:00000000  
0000000:0000000000100000
```

To make this number a little more user-friendly, we translate it into hexadecimal, again 8 octets separated by a colon, for example:

```
2001:0db8:0000:0002:0000:0000:0000:0020
```

We can further simplify the above address. Because any four-digit group of zeros within an IPv6 address may be reduced to a single zero or altogether omitted, the above address can be reduced to:

```
2001:0db8:0000:0002:0:0:0:20
```

or

```
2001:db8:0:2::20
```

## IPv6 packet structure

Each IPv6 packet consists of a mandatory fixed header and optional extension headers, and carries a payload, which is typically either a datagram and/or Transport Layer information. The

payload could also contain data for the Internet Layer or Link Layer. Unlike IPv4, IPv6 packets aren't fragmented by routers, requiring hosts to implement Maximum Transmission Unit (MTU) Path Discovery for MTUs larger than the smallest MTU (which is 1280 octets).

## Jumbograms and jumbo payloads

In IPv6, packets which exceed the MTU of the underlying network are labelled jumbograms, which consist of a jumbo payload. A jumbogram typically exceeds the IP MTU size limit of 65,535 octets, and provides the jumbo payload option, which can allow up to nearly 4GiB of payload data, as defined in [RFC 2675](#). When the MTU is determined to be too large, the receiving host sends a 'Packet too Big' ICMPv6 type 2 message to the sender.

## Fragmentation and reassembly

As noted, packets that are too large for the MTU require hosts to perform MTU Path Discovery to determine the maximum size of packets to send. Packets that are too large require a 'Fragment' extension header, to divide the payload into segments that are 8 octets in length (except for the last fragment, which is smaller). Packets are reassembled according to the extension header and the fragment offset.

## Benefits of IPv6

Some of the benefits of IPv6 include:

- More efficient routing
- Reduced management requirement
- Stateless auto-reconfiguration of hosts
- Improved methods to change Internet Service Providers
- Better mobility support
- Multi-homing
- Security
- Scoped address: link-local, site-local, and global address space

# IPv6 Features

In order to configure IPv6 features using the web-based manager, IPv6 must be enabled using Feature Select. Go to *System > Config > Features*, enable IPv6, and click *Apply*.

The following IPv6 features are available from the FortiOS 5.0 web-based manager:

- IPv6 policies
- IPv6 Network Address Translation
- ICMPv6
- IPv6 in dynamic routing
- Dual stack routing
- IPv6 tunnelling
- SIP over IPv6
- New Fortinet FortiGate IPv6 MIB fields
- IPv6 Per-IP traffic shaper
- DHCPv6
- IPv6 forwarding—Policies, IPS, Application Control, flow-based antivirus, web filtering, and DLP
- FortiGate interfaces can get IPv6 addresses from an IPv6 DHCP server

## IPv6 policies

IPv6 security policies are created both for an IPv6 network and a transitional network. A transitional network is a network that is transitioning over to IPv6 but must still have access to the Internet or must connect over an IPv4 network.

These policies allow for this specific type of traffic to travel between the IPv6 and IPv4 networks. The IPv6 options for creating these policies is hidden by default. You must enable this feature under *System > Config > Features*.

**Figure 285:**IPv6 policy route

## IPv6 policy routing

IPv6 policy routing functions in the same way as IPv4 policy routing. To add an IPv6 policy route, go to *Router > Static > Policy Routes* and select *Create New > IPv6 Policy Route*.

**Figure 286:** Adding an IPv6 Policy route

You can also use the following command to add IPv6 policy routes:

```
config router policy6
  edit 0
    set input-device <interface>
    set src <ipv6_ip>
    set dst <ipv6_ip>
    set protocol <0-255>
    set gateway <ipv6_ip>
    set output-device <interface>
    set tos <bit_pattern>
    set tos-mask <bit_mask>
  end
```

## IPv6 security policies

IPv6 security policies now support all the features supported by IPv4 security policies. The following new features were added in FortiOS 5.0:

- Policy types and subtypes.
- NAT support including using the destination interface IP address, fixed port, and dynamic IP pools.
- All security features (antivirus, web filtering, application control, IPS, email filtering, DLP, VoIP, and ICAP).
- All traffic shaping options, including: shared traffic shaping, reverse shared traffic shaping, and per-IP traffic shaping.
- All user and device authentication options.

## IPv6 explicit web proxy

With FortiOS 5.0, you can use the explicit web proxy for IPv6 traffic. To do this you need to:

- Enable the Explicit Proxy from the dashboard.
- Enable the IPv6 explicit web proxy from the CLI.
- Enable the explicit web proxy for one or more FortiGate interfaces. These interfaces also need IPv6 addresses.
- Add IPv6 web proxy security policies to allow the explicit web proxy to accept IPv6 traffic.

Use the following steps to set up a FortiGate unit to accept IPv6 traffic for the explicit web proxy at the Internal interface and forward IPv6 explicit proxy traffic out the wan1 interface to the Internet.

1. Go to *System > Dashboard > Status* and turn on *Explicit Proxy* under the *Features > Security Features* widget.
2. Enter the following CLI command to enable the IPv6 explicit web proxy:
 

```
config web-proxy explicit
  set status enable
  set ipv6-status enable
end
```
3. Go to *System > Network > Interfaces* and edit the *internal* interface, select *Enable Explicit Web Proxy* and select *OK*.
4. Go to *Policy > Policy > IPv6 Policy* and select *Create New* to add an IPv6 explicit web proxy security policy with the following settings shown in [Figure 287](#).

This IPv6 explicit web proxy policy allows traffic from all IPv6 IP addresses to connect through the explicit web proxy and through the wan1 interface to any IPv6 addresses that are accessible from the wan1 interface.

If you have enabled both the IPv4 and the IPv6 explicit web proxy, you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

**Figure 287:**Example IPv6 Explicit Web Proxy security policy

New Policy	
Policy Type	<input checked="" type="radio"/> Firewall <input type="radio"/> VPN
Policy Subtype	<input checked="" type="radio"/> Address <input type="radio"/> User Identity <input type="radio"/> Device Identity
Incoming Interface	web-proxy
Source Address	Click to add...
Source IPv6 Address	all
Outgoing Interface	port2
Destination Address	Click to add...
Destination IPv6 Address	all
Schedule	always
Service	webproxy
Action	ACCEPT

## Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy using only one IPv6 address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require users to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 HTTP proxy, use the following command:

```
config web-proxy explicit
    set incoming-ipv6 2001:db8:0:2::30
end
```

## Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config http-proxy explicit
    set outgoing-ip6 2001:db8:0:2::50
end
```

## VIP64

VIP64 policies can be used to configure static NAT virtual IPv6 address for IPv4 addresses. VIP64 can be configured from the CLI using the following commands:

```
config firewall vip64
    edit <zname_str>
        set arp-reply {enable | disable}
        set color <color_int>
        set comment <comment_str>
        set extip <address_ipv6>[-address_ipv6]
        set extport <port_int>
        set id <id_num_str>
        set mappedip [<start_ipv4>-<end_ipv4>]
        set mappedport <port_int>
        set portforward {enable | disable}
        set src-filter <addr_str>
    endIPv6 for FortiOS 5.0
```

**Table 76:** VIP64 CLI Variables and Defaults

Variable	Description	Default
<zname_str>	Enter the name of this virtual IP address.	No default.
arp-reply {enable   disable}	Select to respond to ARP requests for this virtual IP address.	enable
color <color_int>	Enter the number of the color to use for the group icon in the web-based manager.	0

**Table 76:** VIP64 CLI Variables and Defaults

Variable	Description	Default
comment <comment_str>	Enter comments relevant to the configured virtual IP.	No default.
extip <address_ipv6>[-address_ipv6]	<p>Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network.</p> <p>If mappedip is an IP address range, the FortiGate unit uses extip as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>To configure a dynamic virtual IP that accepts connections destined for any IP address, set extip to ::.</p>	::
extport <port_int>	<p>Enter the external port number that you want to map to a port number on the destination network.</p> <p>This option only appears if portforward is enabled.</p> <p>If portforward is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set extport to the first port number in the range. Then set mappedport to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the extport port number range.</p>	0
id <id_num_str>	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.

**Table 76:** VIP64 CLI Variables and Defaults

Variable	Description	Default
mappedip [<start_ipv4>-<end_ipv4>]	<p>Enter the IP address or IP address range on the destination network to which the external IP address is mapped.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as a single IP address to create a one-to-many mapping.</p>	0.0.0.0
mappedport <port_int>	<p>Enter the port number on the destination network to which the external port number is mapped.</p> <p>You can also enter a port number range to forward packets to multiple ports on the destination network.</p> <p>For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.</p>	0
portforward {enable   disable}	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring <code>extport</code> and <code>mappedport</code> .	disable
src-filter <addr_str>	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x:x:x:x:x:x/n). Separate addresses with spaces.	null

## VIP46

VIP46 policies can be used to configure static NAT virtual IPv4 address for IPv6 addresses. VIP46 can be configured from the CLI using the following commands (see the table below for variable details):

```
config firewall vip46
  edit <name_str>
    set arp-reply {enable | disable}
    set color <color_int>
    set comment <comment_str>
    set extip <address_ipv4>[-address_ipv4]
    set extport <port_int>
    set id <id_num_str>
    set mappedip [<start_ipv6>-<end_ipv6>]
    set mappedport <port_int>
    set portforward {enable | disable}
    set src-filter <add_str>
  end
```

**Table 77:**VIP46 CLI Variables and Defaults

Variable	Description	Default
<name_str>	Enter the name of this virtual IP address.	No default.
arp-reply {enable   disable}	Select to respond to ARP requests for this virtual IP address.	enable
color <color_int>	Enter the number of the color to use for the group icon in the web-based manager.	0
comment <comment_str>	Enter comments relevant to the configured virtual IP.	No default.
extip <address_ipv4>[-address_ipv4]	<p>Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network.</p> <p>If mappedip is an IP address range, the FortiGate unit uses extip as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>To configure a dynamic virtual IP that accepts connections destined for any IP address, set extip to 0.0.0.0.</p>	0.0.0.0

**Table 77:** VIP46 CLI Variables and Defaults

Variable	Description	Default
extport <port_int>	<p>Enter the external port number that you want to map to a port number on the destination network.</p> <p>This option only appears if <code>portforward</code> is enabled.</p> <p>If <code>portforward</code> is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set <code>extport</code> to the first port number in the range. Then set <code>mappedport</code> to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the <code>extport</code> port number range.</p>	0
id <id_num_str>	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.
mappedip [<start_ipv6>-<end_ipv6>]	<p>Enter the IP address or IP address range on the destination network to which the external IP address is mapped.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping.</p> <p>If <code>mappedip</code> is an IP address range, the FortiGate unit uses <code>extip</code> as a single IP address to create a one-to-many mapping.</p>	::
mappedport <port_int>	<p>Enter the port number on the destination network to which the external port number is mapped.</p> <p>You can also enter a port number range to forward packets to multiple ports on the destination network.</p> <p>For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.</p>	0
portforward {enable   disable}	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring <code>extport</code> and <code>mappedport</code> .	disable
src-filter <addr_str>	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x.x.x.x/n). Separate addresses with spaces.	null

## IPv6 Network Address Translation

NAT66, NAT64, and DNS64 are now supported for IPv6. These options provide IPv6 NAT and DNS capabilities with IPv6-IPv4 tunnelling or dual stack configurations. The commands are available only in the CLI.

Fortinet supports all features described in [RFC 6146](#). However, for DNS64 there is no support for handling Domain Name System Security Extensions (DNSSEC). DNSSEC is for securing types of information that are provided by the DNS as used on an IP network or networks. You can find more information about DNS64 in [RFC 6147](#).

### NAT64 and DNS64 (DNS proxy)

NAT64 is used to translate IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. 'DNS proxy' and 'DNS64' are interchangeable terms.

**Figure 288:**Example NAT64 configuration

With a NAT64 and DNS64 configuration in place on a FortiGate unit, clients on an IPv6 network can transparently connect to addresses on an IPv4 network. NAT64 and DNS64 perform the IPv4 to IPv6 transition, allowing clients that have already switched to IPv6 addresses to continue communicating with servers that still use IPv4 addresses.

To enable NAT64 and DNS64, use the following CLI command:

```
config system nat64
    set status enable
end
```

### NAT64 policies

You can configure security policies for NAT64 using the web-based manager. For these options to appear, the feature must be enabled using *Feature Select*. You can then configure the policies under *Policy > Policy > NAT64 Policy*.

NAT64 policies and can also be configured from the CLI using the following command:

```
config firewall policy64
```

In the following section, you will configure a NAT64 policy that allows connections from an internal IPv6 network to an external IPv4 network.

### To configure NAT64 to allow a host on the IPv6 network to connect to the Internet server

In this example, the Internal IPv6 network address is 2001:db8:1::/48 and the external IPv4 network address is 172.20.120.0/24. NAT64 is configured to allow a user on the internal network to connect to the server at IPv4 address 172.20.120.12. In this configuration, sessions exiting the wan1 interface must have their source address changed to an IPv4 address in the range 172.20.120.200 to 172.20.120.210.

1. Enter the following command to enable NAT64.

```
config system nat64
    set status enable
end
```

Enabling NAT64 with the `config system nat64` command means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is not enabled. With this setting disabled, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

By using the `nat64-prefix` option of the `config system nat64` command to change the default nat64 prefix from the well-known prefix of 64:ff9b::/96 and setting `always-synthesize-aaaa-record` to *enable*, the DNS proxy does not check for AAAA records but rather synthesizes AAAA records.

As an alternative to the above entry, there is the optional configuration that would allow the resolution of CNAME queries.

```
config system nat64
    set status enable
    set nat64-prefix 64:ff9b::/96
    set always-synthesize-aaaa-record enable
end
```

2. Enter the following command to add an IPv6 firewall address for the internal network:

```
config firewall address6
    edit internal-net6
        set ip6 2001:db8::/48
    end
```

3. Enter the following command to add an IPv4 firewall address for the external network:

```
config firewall address
    edit external-net4
        set subnet 172.20.120.0/24
        set associated-interface wan1
    end
```

4. Enter the following command to add an IP pool containing the IPv4 address that the should become the source address of the packets exiting the wan1 interface:

```
config firewall ippool
  edit exit-pool4
    set startip 172.20.120.200
    set endip 172.20.120.210
  end
```

5. Enter the following command to add a NAT64 policy that allows connections from the internal IPv6 network to the external IPv4 network:

```
config firewall policy64
  edit 0
    set srcintf internal
    set srcaddr internal-net6
    set dstintf wan1
    set dstaddr external-net4
    set action accept
    set schedule always
    set service ANY
    set logtraffic enable
    set ippool enable
    set poolname exit-pool4
  end
```

The `srcaddr` can be any IPv6 firewall address and the `dstaddr` can be any IPv4 firewall address.

Other NAT64 policy options include `fixedport`, which can be used to prevent NAT64 from changing the destination port. You can also configure traffic shaping for NAT64 policies.

#### **How a host on the internal IPv6 network communicates with example.server.com that only has IPv4 address on the Internet**

1. The host on the internal network does a DNS lookup for example.server.com by sending a DNS query for an AAAA record for example.server.com.
2. The DNS query is intercepted by the FortiGate DNS proxy.
3. The DNS proxy attempts to resolve the query with a DNS server on the Internet and discovers that there are no AAAA records for example.server.com.

The previous step is skipped if `always-synthesize-aaaa-record` is enabled.

4. The DNS proxy performs an A-record query for example.server.com and gets back an RRSets containing a single A record with the IPv4 address 172.20.120.12.
5. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is 64:ff9b::172.20.120.12.

6. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address 64:ff9b::172.20.120.12.
7. The packet is routed to the FortiGate internal interface where it is accepted by the NAT64 security policy.
8. The FortiGate unit translates the destination address of the packets from IPv6 address 64:ff9b::172.20.120.12 to IPv4 address 172.20.120.12 and translates the source address of the packets to 172.20.120.200 (or another address in the IP pool range) and forwards the packets out the wan1 interface to the Internet.

## NAT66

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS 5.0, NAT66 options can be added to an IPv6 security policy from the CLI.

Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy. For example, use the following command to add an IPv6 security policy that translates the source address of IPv6 packets to the address of the destination interface (similar to IPv4 source NAT):

```
config firewall policy6
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr internal_net
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
  end
```

It's also useful to translate one IPv6 source address to another address that is not the same as the address of the exiting interface. You can do this using IP pools. For example, enter the following command to add an IPv6 IP pool containing one IPv6 IP address:

```
configure firewall ippool6
  edit example_6_pool
    set startip 2001:db8::
    set endip 2001:db8::
  end
```

Enter the following command to add an IPv6 firewall address that contains a single IPv6 IP address.

```
configure firewall address6
  edit device_address
    set ip6 2001:db8::132/128
  end
```

Enter the following command to add an IPv6 security policy that accepts packets from a device with IP address 2001:db8::132 and translates the source address to 2001:db8::.

```
config firewall policy6
edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr device_address
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
    set ippool enable
    set poolname example_6_pool
end
```

### NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, enter the following command to add an IPv6 virtual IP that maps the destination address 2001:db8::dd to 2001:db8::ee

```
configure firewall vip6
edit example-vip6
    set extip 2001:db8::dd
    set mappedip 2001:db8::ee
end
```

Enter the following command to add an IPv6 security policy that accepts packets with a destination address 2001:db8::dd and translates that destination address to 2001:db8::ee

```
config firewall policy6
edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr all
    set dstaddr example-vip6
    set action accept
    set schedule always
    set service ANY
end
```

### NAT64 and NAT66 session failover

The FortiGate Clustering Protocol (FGCP) supports IPv6, NAT64, and NAT66 session failover. If session pickup is enabled, these sessions are synchronized between cluster members and, after an HA failover, the sessions will resume with only minimal interruption.

## NAT46

NAT46 is used to translate IPv4 addresses to IPv6 addresses so that a client on an IPv4 network can communicate transparently with a server on an IPv6 network.

To enable NAT46, use the following CLI command:

```
config system nat46
    set status enable
end
```

### NAT46 policies

Security policies for NAT46 can be configured from the web-based manager. For these options to appear in the web-based manager, this feature must be enabled using *Feature Select*. You can then configure the policies under *Policy > Policy > NAT46 Policy*.

NAT46 policies can also be configured from the CLI using the following command:

```
config firewall policy46
```

## ICMPv6

Internet Control Message Protocol version 6 (ICMPv6) is the new implementation of the Internet Control Message Protocol (ICMP) that is part of Internet Protocol version 6 (IPv6). The ICMPv6 protocol is defined in [RFC 4443](#).

ICMPv6 is a multipurpose protocol. It performs such things as:

- error reporting in packet processing
- diagnostic functions
- Neighbor Discovery process
- IPv6 multicast membership reporting

It is also designed as a framework to use extensions for use with future implementations and changes.

Examples of extensions that have already been written for ICMPv6:

- Neighbor Discovery Protocol (NDP) - a node discovery protocol in IPv6 which replaces and enhances functions of ARP.
- Secure Neighbor Discovery Protocol (SEND) - an extension of NDP with extra security.
- Multicast Router Discovery (MRD) - allows discovery of multicast routers.

ICMPv6 messages use IPv6 packets for transportation and can include IPv6 extension headers. ICMPv6 includes some of the functionality that in IPv4 was distributed among protocols such as ICMPv4, ARP (Address Resolution Protocol), and IGMP (Internet Group Membership Protocol version 3).

ICMPv6 has simplified the communication process by eliminating obsolete messages.

ICMPv6 messages are subdivided into two classes: error messages and information messages.

Error Messages are divided into four categories:

- Destination Unreachable
- Time Exceeded
- Packet Too Big
- Parameter Problems

Information messages are divided into three groups:

- Diagnostic messages
- Neighbor Discovery messages
- Messages for the management of multicast groups.

## ICMPv6 Types and Codes

ICMPv6 has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

Type codes 0 – 127 are error messages and type codes 128 – 255 are for information messages.

**Table 78:**ICMPv6 Types and Codes

Type Number	Type Name	Code
0	Reserved	0 - no route to destination 1 - communication with destination administratively prohibited 2 - beyond scope of source address 3 - address unreachable 4 - port unreachable 5 - source address failed ingress/egress policy 6 - reject route to destination 7 - Error in Source Routing Header
1	Destination Unreachable	
2	Packet Too Big	
3	Time Exceeded	0 - hop limit exceeded in transit 1 - fragment reassembly time exceeded
4	Parameter Problem	0 - erroneous header field encountered 1 - unrecognized Next Header type encountered 2 - unrecognized IPv6 option encountered
100	Private Experimentation	
101	Private Experimentation	
102 - 126	Unassigned	
127	Reserved for expansion if ICMPv6 error messages	
128	Echo Request	

**Table 78:**ICMPv6 Types and Codes (continued)

Type Number	Type Name	Code
129	Echo Replay	
130	Multicast Listener Query	
131	Multicast Listener Report	
132	Multicast Listener Done	
133	Router Solicitation	
134	Router Advertisement	
135	Neighbor Solicitation	
136	Neighbor Advertisement	
137	Redirect Message	
138	Router Renumbering	0 - Router Renumbering Command 1 - Router Renumbering Result 255 - Sequence Number Reset
139	ICMP Node Information Query	0 - The Data field contains an IPv6 address which is the Subject of this Query. 1 - The Data field contains a name which is the Subject of this Query, or is empty, as in the case of a NOOP. 2 - The Data field contains an IPv4 address which is the Subject of this Query. 140 ICMP Node Information Response 0 - A successful reply. The Reply Data field may or may not be empty. 1 - The Responder refuses to supply the answer. The Reply Data field will be empty. 2 - The Qtype of the Query is unknown to the Responder. The Reply Data field will be empty.
140	ICMP Node Information Response	0 - A successful reply. The Reply Data field may or may not be empty. 1 - The Responder refuses to supply the answer. The Reply Data field will be empty. 2 - The Qtype of the Query is unknown to the Responder. The Reply Data field will be empty.

**Table 78:**ICMPv6 Types and Codes (continued)

Type Number	Type Name	Code
141	Inverse Neighbor Discovery Solicitation Message	
142	Inverse Neighbor Discovery Advertisement Message	
143	Version 2 Multicast Listener Report	
144	Home Agent Address Discovery Request Message	
145	Home Agent Address Discovery Reply Message	
146	Mobile Prefix Solicitation	
147	Mobile Prefix Advertisement	
148	Certification Path Solicitation Message	
149	Certification Path Advertisement Message	
150	ICMP messages utilized by experimental mobility protocols such as Seamoby	
151	Multicast Router Advertisement	
152	Multicast Router Solicitation	
153	Multicast Router Termination	
154	FMIPv6 Messages	
155	RPL Control Message	
156	ILNPv6 Locator Update Message	
157	Duplicate Address Request	

**Table 78:**ICMPv6 Types and Codes (continued)

Type Number	Type Name	Code
158	Duplicate Address Confirmation	
159 – 199	Unassigned	
200	Private experimentation	
201	Private experimentation	
255	Reserved for expansion of ICMPv6 informational messages	

## IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in *System > Config > Features*. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

## Dual stack routing

Dual stack routing implements dual IP layers in hosts and routers, supporting both IPv6 and IPv4. A dual stack architecture supports both IPv4 and IPv6 traffic and routes the appropriate traffic as required to any device on the network. Administrators can update network components and applications to IPv6 on their own schedule, and even maintain some IPv4 support indefinitely if that is necessary. Devices that are on this type of network, and connect to the Internet, can query Internet DNS servers for both IPv4 and IPv6 addresses. If the Internet site supports IPv6, the device can easily connect using the IPv6 address. If the Internet site does not support IPv6, then the device can connect using the IPv4 addresses.

In FortiOS, dual stack architecture it is not comprised merely of basic addressing functions that operate in both versions of IP. The other features of the appliance, such as UTM and routing, can also use both IP stacks.

If an organization with a mixed network uses an Internet service provider that does not support IPv6, they can use an IPv6 tunnel broker to connect to IPv6 addresses that are on the Internet. FortiOS supports IPv6 tunnelling over IPv4 networks to tunnel brokers. The tunnel broker extracts the IPv6 packets from the tunnel and routes them to their destinations.

## IPv6 tunnelling

IPv6 Tunnelling is the act of tunnelling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than Network Address Translation (NAT) because, once the packet reaches its final destination, the true originating address of the sender will still be readable. The IPv6 packets are encapsulated within packets with IPv4 headers, which carry their IPv6 payload through the IPv4 network.

The key to IPv6 tunnelling is the ability of the two devices, whether they are a host or a network device, to be dual stack compatible in order to work with both IPv4 and IPv6 at the same time. In the process, the entry node of the tunnel portion of the path will create an encapsulating IPv4 header and transmit the encapsulated packet. The exit node at the end of the tunnel receives the encapsulated packet. The IPv4 header is removed, the IPv6 header is updated, and the IPv6 packet is processed.

There are two types of tunnels in IPv6:

**Automatic tunnels:** Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address – the IPv6 address of the destination host includes information about which IPv4 address the packet should be tunneled to.

**Configured tunnels:** Configured tunnels must be configured manually. These tunnels are used when using IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the endpoints of the tunnel must be specified.

### Tunnel configuration

There are a few ways in which the tunnelling can be performed depending on which segment of the path between the end points of the session the encapsulation takes place.

**Host to Host:** Dual Stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans the entire path taken by the IPv6 packets.

**Network Device to Host:** Dual Stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. This tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

Use the following command to tunnel IPv6 traffic over an IPv4 network. The IPv6 interface is configured under `config system interface`. The command to do the

reverse is `config system ipv6-tunnel`. These commands are not available in Transparent mode.

```
config system sit-tunnel
  edit <tunnel name>
    set destination <tunnel _address>
    set interface <name>
    set ip6 <address_ipv6>
    set source <address_ipv4>
  end
```

Variable	Description	Default
edit <tunnel_name>	Enter a name for the IPv6 tunnel.	No default.
destination <tunnel_address>	The destination IPv4 address for this tunnel.	0.0.0.0
interface <name>	The interface used to send and receive traffic for this tunnel.	No default.
ip6 <address_ipv6>	The IPv6 address for this tunnel.	No default.
source <address_ipv4>	The source IPv4 address for this tunnel.	0.0.0.0

## Tunnelling IPv6 through IPsec VPN

A variation on tunnelling IPv6 through IPv4 is to use an IPsec VPN tunnel between two FortiGate devices. FortiOS supports IPv6 over IPSec. In this sort of scenario, two networks using IPv6 behind FortiGate units are separated by the Internet, which uses IPv4. An IPsec VPN tunnel is created between the FortiGate units and a tunnel is created over the IPv4-based Internet, but the traffic in the tunnel is IPv6. This has the additional advantage of securing the traffic.

For configuration information, see [IPv6 IPsec VPN](#).

## SIP over IPv6

FortiOS supports Sessions Initiate Protocol (SIP) over IPv6. The SIP application-level gateway (ALG) can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown below, a SIP phone connects to the Internet through a FortiGate unit operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate unit has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.

To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

## New Fortinet FortiGate IPv6 MIB fields

The following IPv6 MIB fields have been added to the Fortinet FortiGate MIB. These MIB entries can be used to display IPv6 session and policy statistics.

- IPv6 Session Counters:
  - `fgSysSes6Count`
  - `fgSysSes6Rate1`
  - `fgSysSes6Rate10`
  - `fgSysSes6Rate30`
  - `fgSysSes6Rate60`
- IPv6 Policy Statistics:
  - `fgFwPol6StatsTable`
  - `fgFwPol6StatsEntry`
  - `FgFwPol6StatsEntry`
  - `fgFwPol6ID`
  - `fgFwPol6PktCount`
  - `fgFwPol6ByteCount`
- IPv6 Session Statistics:
  - `fgIp6SessStatsTable`
  - `fgIp6SessStatsEntry`
  - `FgIp6SessStatsEntry`
  - `fgIp6SessNumber`

The `fgSysSesCount` and `fgSysSesRateX` MIBs report statistics for IPv4 plus IPv6 sessions combined. This behavior was not changed.

## New OIDs

The following OIDs have been added:

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgSystem.fgSystemInfo

.fgSysSes6Count 1.3.6.1.4.1.12356.101.4.1.15

.fgSysSesRate1 1.3.6.1.4.1.12356.101.4.1.16

.fgSysSesRate10 1.3.6.1.4.1.12356.101.4.1.17

.fgSysSesRate30 1.3.6.1.4.1.12356.101.4.1.18

.fgSysSesRate60 1.3.6.1.4.1.12356.101.4.1.19

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwPolicies.fgFwPolTables

.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ID 1.3.6.1.4.1.12356.101.5.1.2.2.1.1

.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6PktCount 1.3.6.1.4.1.12356.101.5.1.2.2.1.2

.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ByteCount 1.3.6.1.4.1.12356.101.5.1.2.2.1.3

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgInetProto.fgInetProtoTables

.fgIp6SessStatsTable.fgIp6SessStatsEntry.fgIp6SessNumber 1.3.6.1.4.1.12356.101.11.2.3.1.1

## EXAMPLE SNMP get/walk output

```
// Session6 stats excerpt from sysinfo:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.4
FORTINET-FORTIGATE-MIB::fgSysSes6Count.0 = Gauge32: 203
FORTINET-FORTIGATE-MIB::fgSysSes6Rate1.0 = Gauge32: 10 Sessions
      Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate10.0 = Gauge32: 2 Sessions
      Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate30.0 = Gauge32: 1 Sessions
      Per Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate60.0 = Gauge32: 0 Sessions
      Per Second

// FwPolicy6 table:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.5.1.2.2
FORTINET-FORTIGATE-MIB::fgFwPol6ID.1.3 = INTEGER: 3
FORTINET-FORTIGATE-MIB::fgFwPol6ID.1.4 = INTEGER: 4
FORTINET-FORTIGATE-MIB::fgFwPol6PktCount.1.3 = Counter64: 4329
FORTINET-FORTIGATE-MIB::fgFwPol6PktCount.1.4 = Counter64: 0
FORTINET-FORTIGATE-MIB::fgFwPol6ByteCount.1.3 = Counter64: 317776
FORTINET-FORTIGATE-MIB::fgFwPol6ByteCount.1.4 = Counter64: 0

// IP6SessNumber:
snmpwalk -v2c -cpublic 192.168.1.111
      1.3.6.1.4.1.12356.101.11.2.3.1
FORTINET-FORTIGATE-MIB::fgIp6SessNumber.1 = Counter32: 89
```

## IPv6 Per-IP traffic shaper

You can add any Per-IP traffic shaper to an IPv6 security policy using the following command:

```
config firewall policy6
  edit 0
    set per-ip-shaper "new-perip-shaper"
  end
```

## DHCPv6

You can use DHCP with IPv6 using the CLI. Use the CLI command

```
config system dhcp6.
```

For more information on the configuration options, see the [CLI Reference](#).

## DHCPv6 relay

You can use the following command to configure a FortiGate interface to relay DHCPv6 queries and responses from one network to a network with a DHCPv6 server and back.

The command enables DHCPv6 relay and includes adding the IPv6 address of the DHCP server that the FortiGate unit relays DHCPv6 requests to:

```
config system interface
edit internal
config ipv6
set dhcp6-relay-service enable
set dhcp6-relay-type regular
set dhcp6-relay-ip 2001:db8:0:2::30
end
```

## IPv6 forwarding—Policies, IPS, Application Control, flow-based antivirus, web filtering, and DLP

FortiOS 5.0 fully supports flow-based inspection of IPv6 traffic. This includes full support for IPS, application control, virus scanning, and web filtering.

To add flow-based inspection to IPv6 traffic go to *Policy > Policy > IPv6 Policy* and select *Create New* to add an IPv6 Security Policy. Configure the policy to accept the traffic to be scanned. Select *Security Profiles* and select the profiles to apply to the traffic.

## FortiGate interfaces can get IPv6 addresses from an IPv6 DHCP server

From the CLI, you can configure any FortiGate interface to get an IPv6 address from an IPv6 DHCP server. For example, to configure the wan2 interface to get an IPv6 address from an IPv6 DHCP server enter the following command:

```
config system interface
edit wan2
config ipv6
set ip6-mode dhcp
end
end
```

# IPv6 Configuration

This section contains configuration information for IPv6 on FortiOS. Attempts are made to include scenarios in each section to better assist with the configuration and to orient the information toward a particular task.

You will find information on the following:

- [IPv6 address groups](#)
- [IPv6 firewall addresses](#)
- [ICMPv6](#)
- [IPv6 IPsec VPN](#)
- [BGP and IPv6](#)
- [RIPng — RIP and IPv6](#)
- [IPv6 IPS](#)
- [Blocking IPv6 packets by extension headers](#)
- [IPv6 Denial of Service policies](#)
- [Configure hosts in an SNMP v1/2c community to send queries or receive traps](#)
- [IPv6 PIM sparse mode multicast routing](#)

## IPv6 address groups

### To create IPv6 address groups from existing IPv6 addresses - web-based manager

Your company has 3 internal servers with IPv6 addresses that it would like to group together for the purposes of a number of policies.

The preconfigured addresses to use will consist of:

- Web\_Server-1
- Web\_Server-2
- Web\_Server-3

Go to *Firewall Objects > Address > Groups* and select *Create New > IPv6 Address Group*.

Fill out the fields with the following information

<b>Group Name</b>	Web_Server_Cluster
<b>Members</b>	Web_Server-1
	Web_Server-2
	Web_Server-3

Select *OK*.

### To create IPv6 address groups from existing IPv6 addresses - CLI

```
config firewall addrgrp6
  edit Web_Server_Cluster
    set member Web_Server-1 Web_Server-2 Web_Server-3
  end
```

### To verify that the addresses were added correctly:

Go to *Firewall Objects > Address > Groups*. Check that the addresses have been added to the address list and that they are correct.

From the CLI, enter the following commands:

```
config firewall addgrp6
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

## IPv6 firewall addresses

### Scenario: Mail Server

You need to create an IPv6 address for the Mail Server on Port1 of your internal network.

- These server is on the network off of port1.
- The IP address is 2001:db8:0:2::20/64
- There should be a tag for this address being for a server

Go to *Firewall Objects > Address > Addresses* and select *Create New > IPv6 Address*.

Fill out the fields with the following information

<b>Address Name</b>	Mail_Server
<b>IPv6 Address</b>	2001:db8:0:2::20/64
<b>Add Tags</b>	Server

Select *OK*.

Enter the following CLI command:

```
config firewall address6
  edit Mail_Server
    set type ipmask
    set subnet 2001:db8:0:2::20/64
    set associated-interface port1
    set tags Server
  end
```

### Scenario: First Floor Network

You need to create an IPv4 address for the subnet of the internal network off of Port1.

- These computers connect to port1.
- The network uses the IPv6 addresses: fdde:5a7d:f40b:2e9d:xxxx:xxxx:xxxx:xxxx
- There should be a reference to this being the network for the 1st floor of the building.

Go to *Firewall Objects > Address > Addresses* and select *Create New > IPv6 Address*.

Fill out the fields with the following information

Field Name	Field Value
Address Name	Internal_Subnet_1
Comments	Network for 1st Floor
Type	Subnet / IP Range
Subnet / IP Range	2001:db8:0:2::/64

Select *OK*.

Enter the following CLI command:

```
config firewall address6
edit Internal_Subnet_1
set comment "Network for 1st Floor"
set subnet 2001:db8:0:2::/64
end
```

**To verify that the addresses were added correctly:**

Go to *Firewall Objects > Address > Addresses*. Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall address6
edit <the name of the address that you wish to verify>
Show full-configuration
```

## ICMPv6

The IT Manager is doing some diagnostics and would like to temporarily block the successful replies of ICMP Node information Responses between 2 IPv6 networks.

The ICMP type for ICMP Node informations responses is 140. The codes for a successful response is 0.

### Web-based Manager Instructions

Go to *Firewall Objects > Service > Services* and select *Create New > Custom Service*.

Fill out the fields with the following information

Field Name	Field Value
Name	diagnostic-test1
Service Type	Firewall
Show in Service List	Enabled
Category	Uncategorized
Protocol Type	ICMP6

<b>Type</b>	140
<b>Code</b>	0

Select *OK*.

Enter the following CLI command:

```
config firewall service custom
edit diagnostic-test1
set protocol ICMP6
set icmptype 140
set icmpcode 0
set visibility enable
end
```

**To verify that the category was added correctly:**

Go to *Firewall Objects > Service > Services*. Check that the services have been added to the services list and that they are correct.

Enter the following CLI command:

```
config firewall service custom
edit <the name of the service that you wish to verify>
show full-configuration
```

## IPv6 IPsec VPN

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality. The following topics are included in this section:

- [Overview of IPv6 IPsec support](#)
- [Configuring IPv6 IPsec VPNs](#)
- [Site-to-site IPv6 over IPv6 VPN example](#)
- [Site-to-site IPv4 over IPv6 VPN example](#)
- [Site-to-site IPv6 over IPv4 VPN example](#)

### Overview of IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can also combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

<b>IPv4 over IPv6</b>	The VPN gateways have IPv6 addresses.  The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors.
<b>IPv6 over IPv4</b>	The VPN gateways have IPv4 addresses.  The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

## Certificates

On a VPN with IPv6 phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

## Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN: phase 1 settings, phase 2 settings, security policies, and routing.

### Phase 1 configuration

In the web-based manager, you define the Phase 1 as IPv6 in the Advanced settings. Enable the IPv6 Version check box. You can then enter an IPv6 address for the remote gateway.

In the CLI, you define an IPsec phase 1 configuration as IPv6 by setting `ip-version` to 6. Its default value is 4. Then, the `local-gw` and `remote-gw` keywords are hidden and the corresponding `local-gw6` and `remote-gw6` keywords are available. The values for `local-gw6` and `remote-gw6` must be IPv6 addresses. For example:

```
config vpn ipsec phase1-interface
  edit tunnel6
    set ip-version 6
    set remote-gw6 0:123:4567::1234
    set interface port3
    set proposal 3des-md5
  end
```

### Phase 2 configuration

To create an IPv6 IPsec phase 2 configuration in the web-based manager, you need to define IPv6 selectors in the Advanced settings. Change the default “0.0.0.0/0” address for Source address and Destination address to the IPv6 value “::/0”. If needed, enter specific IPv6 addresses, address ranges or subnet addresses in these fields.

In the CLI, set `src-addr-type` and `dst-addr-type` to `ip6`, `range6` or `subnet6` to specify IPv6 selectors. By default, zero selectors are entered, “::/0” for the `subnet6` address type, for example. The simplest IPv6 phase 2 configuration looks like this:

```
config vpn ipsec phase2-interface
  edit tunnel6_p2
    set phase1name tunnel6
    set proposal 3des-md5
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
```

## Security policies

To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network's port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6.

## Routing

Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them. You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You also need a route to the remote protected network via the IPsec interface.

### To create a static route in the web-based manager:

1. Go to *Router > Static > Static Routes*.  
On some desktop FortiGate models, go to *System > Network > Routing*.
2. Select the drop-down arrow on the *Create New* button and select *IPv6 Route*.
3. Enter the information and select *OK*.

In the CLI, use the `router static6` command. For example, where the remote network is `fec0:0000:0000:0004::/64` and the IPsec interface is `toB`:

```
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toB
    set dst fec0:0000:0000:0004::/64
  next
end
```

If the VPN is IPv4 over IPv6, the route to the remote protected network is an IPv4 route. If the VPN is IPv6 over IPv4, the route to the remote VPN gateway is an IPv4 route.

## Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

To access IPv6 functionality through the web-based manager, go to *System Admin > Settings* and enable *IPv6* in the section, *Display Options on GUI*.

**Figure 285:**Example IPv6-over-IPv6 VPN topology

### Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
  edit port3
    config ipv6
      set ip6-address fec0::0000:209:0fff:fe83:25f3/64
    end
  next
end
```

### Configure FortiGate A IPsec settings

The phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to 6 and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are `0.0.0.0/0` for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
edit toB2
set phase1name toB
set proposal 3des-md5 3des-sha1
set pfs enable
set replay enable
set src-addr-type subnet6
set dst-addr-type subnet6
end
```

## Configure FortiGate A security policies

Security policies are required to allow traffic between `port3` and the IPsec interface `toB` in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```
config firewall policy6
edit 1
set srcintf port3
set dstintf toB
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
next
edit 2
set srcintf toB
set dstintf port3
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
end
```

## Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toB
    set dst fec0:0000:0000:0004::/64
  end
```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0003:209:0fff:fe83:25c7/64
    end
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
  end
config vpn ipsec phase1-interface
  edit toA
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
```

```

end
config firewall policy6
edit 1
set srcintf port3
set dstintf toA
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
next
edit 2
set srcintf toA
set dstintf port3
set srcaddr all6
set dstaddr all6
set action accept
set service ANY
set schedule always
end
config router static6
edit 1
set device port2
set dst 0::/0
next
edit 2
set device toA
set dst fec0:0000:0000:0000::/64
end

```

## Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

**Figure 286:**Example IPv4-over-IPv6 VPN topology

## Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
  edit port3
    set 192.168.2.1/24
  end
```

## Configure FortiGate A IPsec settings

The phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The phase 2 configuration is the same as you would use for an IPv4 VPN. By default, phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
  end
```

## Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  next
```

```

edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
end

```

## Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```

config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toB
        set dst 192.168.3.0/24
    end
end

```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

```

config system interface
    edit port2
        config ipv6
            set ip6-address fec0::0003:fe83:25c7/64
        end
    next
    edit port3
        set 192.168.3.1/24
    end
config vpn ipsec phase1-interface
    edit toA
        set ip-version 6
        set interface port2
        set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
        set dpd enable
        set psksecret maryhadalittlelamb
        set proposal 3des-md5 3des-sha1
    end
end

```

```

end
config vpn ipsec phase2-interface
edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
end
config firewall policy
edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
next
edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
end
config router static6
edit 1
    set device port2
    set dst 0::/0
next
edit 2
    set device toA
    set dst 192.168.2.0/24
end

```

## Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

**Figure 287:**Example IPv6-over-IPv4 VPN topology

### Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
  edit port2
    set 10.0.0.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f3/64
    end
  end
```

### Configure FortiGate A IPsec settings

The phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
  edit toB
    set interface port2
    set remote-gw 10.0.1.1
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The phase 2 configuration uses IPv6 selectors. By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are `0.0.0.0/0` for IPv4, `:::/0` for IPv6.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
```

```

        set pfs enable
        set replay enable
        set src-addr-type subnet6
        set dst-addr-type subnet6
    end

```

## Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. Define the address all6 using the `firewall address6` command as `::/0`.

```

config firewall policy6
    edit 1
        set srcintf port3
        set dstintf toB
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toB
        set dstintf port3
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    end

```

## Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on port2.

```

config router static6
    edit 1
        set device toB
        set dst fec0:0000:0000:0004::/64
    end
config router static
    edit 1
        set device port2
        set dst 0.0.0.0/0
        set gateway 10.0.0.254
    end

```

## Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
    edit port2
        set 10.0.1.1/24
    next
    edit port3
        config ipv6
            set ip6-address fec0::0004:209:0fff:fe83:2569/64
        end
config vpn ipsec phase1-interface
    edit toA
        set interface port2
        set remote-gw 10.0.0.1
        set dpd enable
        set psksecret maryhadalittlelamb
        set proposal 3des-md5 3des-sha1
    end
config vpn ipsec phase2-interface
    edit toA2
        set phase1name toA
        set proposal 3des-md5 3des-sha1
        set pfs enable
        set replay enable
        set src-addr-type subnet6
        set dst-addr-type subnet6
    end
config firewall policy6
    edit 1
        set srcintf port3
        set dstintf toA
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toA
        set dstintf port3
        set srcaddr all6
        set dstaddr all6
        set action accept
        set service ANY
        set schedule always
    end
config router static6
    edit 1
```

```

        set device toA
        set dst fec0:0000:0000:0000::/64
    end
config router static
    edit 1
        set device port2
        set gateway 10.0.1.254
    end

```

## BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`.

IPv6 BGP commands include:

```

config router bgp
    set activate6 {enable | disable}
    set allowas-in6 <max_num_AS_integer>
    set allowas-in-enable6 {enable | disable}
    set as-override6 {enable | disable}
    set attribute-unchanged6 [as-path] [med] [next-hop]
    set capability-default-originate6 {enable | disable}
    set capability-graceful-restart6 {enable | disable}
    set default-originate-route-map6 <routemap_str>
    set distribute-list-in6 <access-list-name_str>
    set distribute-list-out6 <access-list-name_str>
    set filter-list-in6 <aspath-list-name_str>
    set filter-list-out6 <aspath-list-name_str>
    set maximum-prefix6 <prefix_integer>
    set maximum-prefix-threshold6 <percentage_integer>
    set maximum-prefix-warning-only6 {enable | disable}
    set next-hop-self6 {enable | disable}
    set prefix-list-in6 <prefix-list-name_str>
    set prefix-list-out6 <prefix-list-name_str>
    set remove-private-as6 {enable | disable}
    set route-map-in6 <routemap-name_str>
    set route-map-out6 <routemap-name_str>
    set route-reflector-client6 {enable | disable}
    set route-server-client6 {enable | disable}
    set send-community6 {both | disable | extended | standard}
    set soft-reconfiguration6 {enable | disable}
    set unsuppress-map6 <route-map-name_str>
    config network6
    config redistribute6
end

```

## RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

This section includes the following topics:

- [Network layout and assumptions](#)
- [Configuring the FortiGate units system information](#)
- [Configuring RIPng on FortiGate units](#)
- [Configuring other network devices](#)
- [Testing the configuration](#)
- [Debugging IPv6 on RIPng](#)

### Network layout and assumptions

#### Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows.

**Table 76:** Rip example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

**Figure 288:**Network topology for the IPV6 RIPng example

### Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

### Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

#### To configure system information on Router1 - web-based manager

1. Go to *System > Dashboard > Status*.
2. For *Host name*, select *Change*.
3. Enter "Router1".
4. Enable *IPv6* on the GUI.
5. Go to *System > Network > Interfaces*.
6. Edit port1 (internal) interface.
7. Set the following information, and select *OK*.

<b>Alias</b>	internal
<b>IP/Netmask</b>	2002:A0B:6565::/0

<b>Administrative Access</b>	HTTPS SSH PING
<b>Description</b>	Internal RnD network
<b>Administrative Status</b>	Up

8. Edit port2 (ISP) interface.
9. Set the following information, and select *OK*.

<b>Alias</b>	ISP
<b>IP/Netmask</b>	2002:AC14:7865::/0
<b>Administrative Access</b>	HTTPS SSH PING
<b>Description</b>	ISP and internet
<b>Administrative Status</b>	Up

#### To configure system information on Router1 - CLI

```

config system global
    set hostname Router1
    set gui-ipv6 enable
end
config system interface
    edit port1
        set alias internal
        set allowaccess https ping ssh
        set description "Internal RnD network"
        config ipv6
            set ip6-address 2002:a0b:6565::/0
        end
    next
    edit port2
        set alias ISP
        set allowaccess https ping ssh
        set description "ISP and internet"
        config ipv6
            set ip6-address 2002:AC14:7865::
        end
    end
end

```

#### To configure system information on Router2 - web-based manager

1. Go to *System > Dashboard > Status*.
2. For *Host name*, select *Change*.
3. Enter "Router2".
4. Enable *IPv6* on the GUI.
5. Go to *System > Network > Interfaces*.
6. Edit port1 (internal) interface.

7. Set the following information, and select **OK**.

<b>Alias</b>	internal
<b>IP/Netmask</b>	2002:A0B:6566::/0
<b>Administrative Access</b>	HTTPS SSH PING
<b>Description</b>	Internal RnD network
<b>Administrative Status</b>	Up

8. Edit port2 (ISP) interface.  
9. Set the following information, and select **OK**.

<b>Alias</b>	ISP
<b>IP/Netmask</b>	2002:AC14:7866::/0
<b>Administrative Access</b>	HTTPS SSH PING
<b>Description</b>	ISP and internet
<b>Administrative Status</b>	Up

#### To configure system information on Router2 - CLI

```
config system global
    set hostname Router2
    set gui-ipv6 enable
end
config system interface
    edit port1
        set alias internal
        set allowaccess https ping ssh
        set description "Internal RnD network"
        config ipv6
            set ip6-address 2002:a0b:6566::/0
        end
    next
    edit port2
        set alias ISP
        set allowaccess https ping ssh
        set description "ISP and internet"
        config ipv6
            set ip6-address 2002:AC14:7866::
        end
    end
end
```

## Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

#### **To configure RIPng on Router1 - CLI**

```
config router ripng
  config interface
    edit port1
    next
    edit port2
    end
  config neighbor
    edit 1
      set interface port1
      set ipv6 2002:a0b:6566::/0
    next
    edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
    end
```

#### **To configure RIPng on Router2 - CLI**

```
config router ripng
  config interface
    edit port1
    next
    edit port2
    end
  config neighbor
    edit 1
      set interface port1
      set ipv6 2002:a0b:6565::/0
    next
    edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
    end
```

### **Configuring other network devices**

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

## Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the [Troubleshooting](#) chapter.

## Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

```
get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

## Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

- turn on debugging in general
- set the debug level to information, a verbose reporting level
- turn on all rip router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

## IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create an normal IPS sensor and assign it to the IPv6 interface policy.

```
config firewall interface-policy6
    edit 1
        set interface "port1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set service6 "ANY"
        set ips-sensor-status enable
        set ips-sensor "all_default"
    next
end
```

## Blocking IPv6 packets by extension headers

FortiOS can now block IPv6 packets based on the extension headers, using the CLI syntax

```
config firewall ipv6-eh-filter.
```

The following commands are now available:

```
set hop-opt {disable | enable}: Block packets with Hop-by-Hop Options header.
set dest-opt {disable | enable}: Block packets with Destination Options header.
set hdopt-type <integer>: Block specific Hop-by-Hop and/or Destination Option types
(maximum 7 types, each between 0 and 255).
set routing {disable | enable}: Block packets with Routing header.
set routing-type <integer>: Block specific Routing header types (maximum 7 types,
each between 0 and 255).
set fragment {disable | enable}: Block packets with Fragment header.
set auth {disable | enable}: Block packets with Authentication header.
set no-next {disable | enable}: Block packets with No Next header.
```

## IPv6 Denial of Service policies

Denial of Service (DoS) policies can now be configured by going to *Policy > Policy > IPv6 Dos Policy*.

## Configure hosts in an SNMP v1/2c community to send queries or receive traps

When you add a host to an SNMP v1/2c community you can now decide whether the FortiGate unit will accept queries from the host or whether the FortiGate unit will send traps to the host.

You can also configure the host for both traps and queries. You can add up to 16 IPv4 hosts and up to 16 IPv6 hosts.

- An IPv4 host that can send queries to the FortiGate unit
- An IPv6 host that the FortiGate unit will send traps to

Use the following command to add two hosts to an SNMP community:

```
config system snmp community
  config hosts
    edit 1
      set interface port1
      set ip 172.20.120.1
      set host-type query
    end
  config hosts6
    edit 1
      set interface port6
      set ip 2001:db8:0:2::30
      set host-type trap
    end
```

## IPv6 PIM sparse mode multicast routing

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with [RFC 4601](#). You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
  set multicast-routing {enable | disable}
  config interface
    edit <interface-name>
      set hello-interval <1-65535 seconds>
      set hello-holdtime <1-65535 seconds>
    end
  config pim-sm-global
    config rp-address
      edit <index>
        set ipv6-address <ipv6-address>
      end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

# Chapter 12 Load Balancing for FortiOS

## 5.0

FortiOS server load balancing includes the features you would expect of any server load balancing solution. Traffic can be distributed across multiple backend servers based on multiple methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer supports HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL or generic TCP/UDP or IP protocols. Session persistence is supported based on the SSL session ID or based on an injected HTTP cookie.

### Before you begin

Before you begin to configure load balancing, take a moment to note the following:

- To be able to configure load balancing from the web-based manager you should begin by going to the System Information dashboard widget and enabling *Load Balance*.

### How this chapter is organized

This document contains detailed information about how to configure firewall server load balancing to load balance various types of traffic to multiple backend servers. This document describes all server load balancing configuration options and contains detailed configuration examples.

This FortiOS Handbook chapter contains the following sections:

[Configuring load balancing](#) describes FortiGate firewall load balancing.

[Load balancing configuration examples](#) describes includes basic and advanced load balancing configurations.

# Configuring load balancing

This section describes how to use the FortiGate firewall load balancing configuration to load balance traffic to multiple backend servers.

This section describes:

- [Load balancing overview](#)
- [Basic load balancing configuration example](#)
- [HTTP and HTTPS load balancing, multiplexing, and persistence](#)
- [SSL/TLS load balancing](#)
- [IP, TCP, and UDP load balancing](#)

## Load balancing overview

You can configure FortiOS load balancing to intercept incoming traffic with a virtual server and share it among one or more backend real servers. By doing so, the FortiGate unit enables multiple real servers to respond as if they were a single device or virtual server. This in turn means that more simultaneous requests can be handled.

**Figure 289:**Load balancing configuration

Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer

4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN. The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

There are additional benefits to load balancing. First, because the load is distributed across multiple servers, the service being provided can be highly available. If one of the servers breaks down, the load can still be handled by the other servers. Secondly, this increases scalability. If the load increases substantially, more servers can be added behind the FortiGate unit in order to cope with the increased load.

## Load balancing, UTM, authentication, and other FortiOS features

Flow-based and proxy-based UTM features such as virus scanning, IPS, DLP, application control, and web filtering can be applied to sessions that are to be load balanced. This includes SSL offloading and multiplexing. Applying these UTM features to load balancing traffic may reduce load balancing performance.

Authentication and dynamic profiles are not supported for load balancing sessions. Usually FortiGate load balancing is used to allow public access to services on servers protected by a FortiGate unit. Authentication is not generally not required for this kind of configuration.

Features such web proxying, web caching, and WAN optimization also do not work with load balanced sessions. However, most other features that can be applied by a security policy are supported.

## Configuring load balancing virtual servers

A virtual server is a specialized firewall virtual IP that performs server load balancing. From the web-based manager you add load balancing virtual server by going to *Firewall Objects > Load Balance > Virtual Server*.

<b>Name</b>	Enter the name for the virtual server.
<b>Color</b>	Select <i>Change</i> beside the icon to change the color of the icon. When you select <i>Change</i> , a color palette window appears; select a color from the palette window.

<b>Type</b>	<p>Select the protocol to be load balanced by the virtual server. If you select a general protocol such as <i>IP</i>, <i>TCP</i>, or <i>UDP</i> the virtual server load balances all <i>IP</i>, <i>TCP</i>, or <i>UDP</i> sessions. If you select specific protocols such as <i>HTTP</i>, <i>HTTPS</i>, or <i>SSL</i> you can apply additional server load balancing features such as <i>Persistence</i> and <i>HTTP Multiplexing</i>.</p> <ul style="list-style-type: none"> <li>• Select <i>HTTP</i> to load balance only <i>HTTP</i> sessions with destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 80 for <i>HTTP</i> sessions). You can also select <i>HTTP Multiplex</i>. You can also set <i>Persistence</i> to <i>HTTP Cookie</i> to select cookie-based persistence.</li> <li>• Select <i>HTTPS</i> to load balance only <i>HTTPS</i> sessions with destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 443 for <i>HTTPS</i> sessions). You can also select <i>Multiplex HTTP requests/responses</i>. You can also set <i>Persistence</i> to <i>HTTP Cookie</i> to select cookie-based persistence. You can also set <i>Persistence</i> to <i>SSL Session ID</i>.</li> <li>• Select <i>IMAPS</i> to load balance only <i>IMAPS</i> sessions with destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 993 for <i>IMAPS</i> sessions). You can also set <i>Persistence</i> to <i>SSL Session ID</i>.</li> <li>• Select <i>POP3S</i> to load balance only <i>POP3S</i> sessions with destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 995 for <i>POP3S</i> sessions). You can also set <i>Persistence</i> to <i>SSL Session ID</i>.</li> <li>• Select <i>SMTPS</i> to load balance only <i>SMTPS</i> sessions with destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 465 for <i>SMTPS</i> sessions). You can also set <i>Persistence</i> to <i>SSL Session ID</i>.</li> <li>• Select <i>SSL</i> to load balance only <i>SSL</i> sessions with destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced.</li> <li>• Select <i>TCP</i> to load balance only <i>TCP</i> sessions with destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced.</li> <li>• Select <i>UDP</i> to load balance only <i>UDP</i> sessions with destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced.</li> <li>• Select <i>IP</i> to load balance all sessions accepted by the security policy that contains this virtual server.</li> </ul>
<b>Interface</b>	Select the virtual server external interface from the list. The external interface is connected to the source network and receives the packets to be forwarded to the destination network.
<b>Virtual Server IP</b>	The IP address of the virtual server. This is an IP address on the external interface that you want to map to an address on the destination network.

<b>Virtual Server Port</b>	Enter the external port number that you want to map to a port number on the destination network. Sessions with this destination port are load balanced by this virtual server.
<b>Load Balance Method</b>	Select the load balancing method used by the virtual server. See <a href="#">“Load balancing methods” on page 1885</a> .
<b>Persistence</b>	Configure persistence to make sure that a user is connected to the same server every time they make a request that is part of the same session. Session persistence is supported for HTTP and SSL sessions. See <a href="#">“Session persistence” on page 1886</a> . For HTTP and HTTPS sessions, see <a href="#">“HTTP and HTTPS persistence” on page 1898</a> .
<b>HTTP Multiplexing</b>	Select to use the FortiGate unit to multiplex multiple client connections into a few connections between the FortiGate unit and the real server. See <a href="#">“HTTP and HTTPS multiplexing” on page 1898</a> .
<b>Preserve Client IP</b>	<p>Select to preserve the IP address of the client in the X-Forwarded-For HTTP header. This can be useful if you want log messages on the real servers to the client’s original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit.</p> <p>This option appears only if <i>HTTP</i> or <i>HTTPS</i> are selected for <i>Type</i>, and is available only if <i>HTTP Multiplexing</i> is selected.</p>
<b>SSL Offloading</b>	Select to accelerate clients’ SSL connections to the server by using the Fortinet FortiGate unit to perform SSL operations, then select which segments of the connection will receive SSL offloading. See <a href="#">“SSL offloading” on page 1903</a>
<b>Certificate</b>	<p>Select the certificate to use with <i>SSL Offloading</i>. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.</p> <p>This option appears only if <i>HTTPS</i> or <i>SSL</i> are selected for <i>Type</i>, and is available only if <i>SSL Offloading</i> is selected.</p>
<b>Health Check</b>	Select which health check monitor configuration will be used to determine a server’s connectivity status. See <a href="#">“Health check monitoring” on page 1888</a> .

From the CLI you configure a virtual server by added a firewall virtual IP and setting the virtual IP type to server load balance:

```
config firewall vip
    edit Vserver-HTTP-1
        set type server-load-balance
    ...
```

A virtual server includes a virtual server IP address bound to an interface. The virtual server IP address is the destination address incoming packets to be load balanced and the virtual server is bound to the interface that receives the packets to be load balanced.

For example, if you want to load balance incoming HTTP traffic from the Internet to a group of web servers on a DMZ network, the virtual server IP address is the known Internet IP address of the web servers and the virtual server binds this IP address to the FortiGate interface connected to the Internet.

When you bind the virtual server’s external IP address to a FortiGate unit interface, by default, the network interface responds to ARP requests for the bound IP address. Virtual servers use proxy ARP, as defined in [RFC 1027](#), so that the FortiGate unit can respond to ARP requests on a network for a real server that is actually installed on another network. In some cases you may

not want the network interface sending ARP replies. You can use the `arp-reply` option disable sending ARP replies:

```
config firewall vip
edit Vserver-HTTP-1
set type server-load-balance
set arp-reply disable
...
```

The load balancing virtual server configuration also includes the virtual server port. This is the TCP port on the bound interface that the virtual server listens for traffic to be load balanced on. The virtual server can listen on any port.

## Load balancing methods

The load balancing method defines how sessions are load balanced to real servers. A number of load balancing methods are available as listed in [Table 77](#).

All load balancing methods will not send traffic to real servers that are down or not responding. However, the FortiGate unit can only determine if a real server is not responding by using a health check monitor. You should always add at least one health check monitor to a virtual server or to individual real servers, or load balancing methods may attempt to distribute sessions to real servers that are not functioning.

**Table 77:** Load balancing methods

Method	Description
<b>Source IP Hash</b>	The traffic load is statically spread evenly across all real servers. However, sessions are not assigned according to how busy individual real servers are. This load balancing method provides some persistence because all sessions from the same source address always go to the same real server. However, the distribution is stateless, so if a real server is added or removed (or goes up or down) the distribution is changed and persistence could be lost.
<b>Round Robin</b>	Directs new requests to the next real server, and treats all real servers as equals regardless of response time or number of connections. Dead real servers or non responsive real servers are avoided.
<b>Weighted</b>	Real servers with a higher weight value receive a larger percentage of connections. Set the real server weight when adding a real server.
<b>First Alive</b>	<p>Always directs sessions to the first alive real server. This load balancing schedule provides real server failover protection by sending all sessions to the first alive real server and if that real server fails, sending all sessions to the next alive real server. Sessions are not distributed to all real servers so all sessions are processed by the “first” real server only.</p> <p>First refers to the order of the real servers in the virtual server configuration. For example, if you add real servers A, B and C in that order, then all sessions always go to A as long as it is alive. If A goes down then sessions go to B and if B goes down sessions go to C. If A comes back up sessions go back to A. Real servers are ordered in the virtual server configuration in the order in which you add them, with the most recently added real server last. If you want to change the order you must delete and re-add real servers in the required order.</p>
<b>Least RTT</b>	Directs sessions to the real server with the least round trip time. The round trip time is determined by a Ping health check monitor and is defaulted to 0 if no Ping health check monitors are added to the virtual server.

**Table 77:** Load balancing methods

Method	Description
<b>Least Session</b>	Directs requests to the real server that has the least number of current connections. This method works best in environments where the real servers or other equipment you are load balancing all have similar capabilities. This load balancing method uses the FortiGate session table to track the number of sessions being processed by each real server. The FortiGate unit cannot detect the number of sessions actually being processed by a real server.
<b>HTTP Host</b>	Load balances HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server.

## Session persistence

Use persistence to make sure that a user is connected to the same real server every time they make an HTTP, HTTPS, or SSL request that is part of the same user session. For example, if you are load balancing HTTP and HTTPS sessions to a collection of eCommerce web servers, when a user is making a purchase they will be starting multiple sessions as they navigate the eCommerce site. In most cases all of the sessions started by this user during on eCommerce session should be processed by the same real server. Typically, the HTTP protocol keeps track of these related sessions using cookies. HTTP cookie persistence makes sure that all sessions that are part of the same user session are processed by the same real server

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the load balance method. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server. For more information about HTTP and HTTPS persistence, see [“HTTP and HTTPS persistence” on page 1898](#).

## Real servers

Add real servers to a load balancing virtual server to provide the information the virtual server requires to be able to send sessions to the server. A real server configuration includes the IP address of the real server and port number that the real server receives sessions on. The FortiGate unit sends sessions to the real server's IP address using the destination port number in the real server configuration.

When configuring a real server you can also specify the weight (used if the load balance method is set to weighted) and you can limit the maximum number of open connections between the FortiGate unit and the real server. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests other real servers until the connection number drops below the specified limit. Setting Maximum Connections to 0 means that the FortiGate unit does not limit the number of connections to the real server.

### Real server active, standby, and disabled modes

By default the real server mode setting is active indicating that the real server is available to receive connections. If the real server is removed from the network (for example, for routine maintenance or because of a hardware or software failure) you can change the mode to standby or disabled. In disabled mode the FortiGate unit no longer sends sessions to the real server.

If a real server is in standby mode the FortiGate also does not send sessions to it unless other real servers added to the same virtual server become unavailable. For example:

- A virtual server that includes two real servers one in active mode and one in standby mode. If the real server in active mode fails, the real server in standby mode is changed to active mode and all sessions are sent to this real server.
- A virtual server includes three real servers, two in active mode and one in standby mode, if one of the real servers in active mode fails, the real server in standby mode is changed to active mode and sessions are load balanced between it and still operating real server. If both real servers in active mode fail, all sessions are sent to the real server in standby mode.

## Adding real servers

To add a real server from the web-based manager go to *Firewall Objects > Load Balance > Real Server*.

<b>Virtual Server</b>	Select the virtual server that will send sessions to this real server.
<b>IP Address</b>	Enter the IP address of the real server.
<b>Port</b>	Enter the port number on the destination network to which the external port number is mapped.
<b>Weight</b>	Enter the weight value of the real server. The higher the weight value, the higher the percentage of connections the server will handle. A range of 1-255 can be used. This option is available only if the associated virtual server's load balance method is <i>Weighted</i> .
<b>Max Connections</b>	<p>Enter the limit on the number of active connections directed to a real server. A range of 1-99999 can be used. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests to another server until the connection number drops below the specified limit.</p> <p>Setting <i>Maximum Connections</i> to 0 means that the FortiGate unit does not limit the number of connections to the real server.</p>
<b>HTTP Host</b>	Enter the HTTP header for load balancing across multiple real servers. This feature is used for load balancing HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server, providing better load balancing for those specific connections.
<b>Mode</b>	Select a mode for the real server.

To add a real server from the CLI you configure a virtual server and add real servers to it. For example, to add three real servers to a virtual server that load balances UDP sessions on port 8190 using weighted load balancing. For each real server the port is not changed. The default real server port is 0 resulting in the traffic being sent the real server with destination port 8190.

Each real sever is given a different weight. Servers with higher weights have a max-connections limit to prevent too many sessions from being sent to them.

```
config firewall vip
  edit Vserver-UDP-1
    set type server-load-balance
    set server-type udp
    set ldb-method weighted
    set extip 172.20.120.30
    set extintf wan1
    set extport 8190
    set monitor ping-mon-1
    config realservers
      edit 1
        set ip 10.31.101.30
        set weight 100
        set max-connections 10000
      next
      edit 2
        set ip 10.31.101.40
        set weight 100
        set max-connections 10000
      next
      edit 3
        set ip 10.31.101.50
        set weight 10
      end
    end
  end
```

## Health check monitoring

From the FortiGate web-based manager you can go to *Firewall Objects > Load Balance > Health Check* and configure health check monitoring so that the FortiGate unit can verify that real servers are able respond to network connection attempts. If a real server responds to connection attempts the load balancer continues to send sessions to it. If a real server stops responding to connection attempts the load balancer assumes that the server is down and does not send sessions to it. The health check monitor configuration determines how the load balancer tests the real servers. You can use a single health check monitor for multiple load balancing configurations.

You can configure TCP, HTTP and Ping health check monitors. Usually you would want the health check monitor to use the same protocol for checking the health of the server as the traffic being load balanced to it. For example, for an HTTP load balancing configuration you would normally use an HTTP health check monitor.

For the TCP and HTTP health check monitors you can specify the destination port to use to connect to the real servers. If you set the port to 0, the health check monitor uses the port defined in the real server. This allows you to use the same health check monitor for multiple real servers using different ports. You can also configure the interval, timeout and retry. A health check occurs every number of seconds indicated by the interval. If a reply is not received within the timeout period the health check is repeated. If no response is received after the number of configured retries, the virtual server is considered unresponsive, and load balancing will disabling traffic to that real server. The health check monitor will continue to contact the real

server and if successful, the load balancer can resume sending sessions to the recovered real server.

For HTTP health check monitors, you can add URL that the FortiGate unit connects to when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.

The URL would not usually include an IP address or domain name. Instead it should start with a “/” and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.31.101.30, the URL “/test\_page.htm” causes the FortiGate unit to send an HTTP get request to “http://10.31.101.30/test\_page.htm”.

For HTTP health check monitors, you can also add a matched content phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the URL option. If the URL returns a web page, the matched content should exactly match some of the text on the web page. You can use the URL and Matched Content options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.

For example, you can set matched content to “server test page” if the real HTTP server page defined by the URL option contains the phrase “server test page”. When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the matched content phrase.

<b>Name</b>	Enter the name of the health check monitor configuration.
<b>Type</b>	Select the protocol used to perform the health check. <ul style="list-style-type: none"><li>• TCP</li><li>• HTTP</li><li>• PING</li></ul>
<b>Port</b>	Enter the port number used to perform the health check. If you set the <i>Port</i> to 0, the health check monitor uses the port defined in the real server. This way you can use a single health check monitor for different real servers.  This option does not appear if the <i>Type</i> is <i>PING</i> .
<b>Interval</b>	Enter the number of seconds between each server health check.
<b>URL</b>	For HTTP health check monitors, add a URL that the FortiGate unit uses when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.  The URL would not usually include an IP address or domain name. Instead it should start with a “/” and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.10.10.1, the <i>URL</i> “/test_page.htm” causes the FortiGate unit to send an HTTP get request to “http://10.10.10.1/test_page.htm”.  This option appears only if <i>Type</i> is <i>HTTP</i> .

<b>Matched Content</b>	<p>For HTTP health check monitors, add a phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the <i>URL</i> option. If the <i>URL</i> returns a web page, the <i>Matched Content</i> should exactly match some of the text on the web page. You can use the <i>URL</i> and <i>Matched Content</i> options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.</p> <p>For example, you can set <i>Matched Content</i> to “server test page” if the real HTTP server page defined by the URL option contains the phrase “server test page”. When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the <i>Matched Content</i> phrase.</p> <p>This option appears only if <i>Type</i> is <i>HTTP</i>.</p>
<b>Timeout</b>	Enter the number of seconds which must pass after the server health check to indicate a failed health check.
<b>Retry</b>	Enter the number of times, if any, a failed health check will be retried before the server is determined to be inaccessible.

### Virtual IP, load balance virtual server and load balance real server limitations

The following limitations apply when adding virtual IPs, Load balancing virtual servers, and load balancing real servers. Load balancing virtual servers are actually server load balancing virtual IPs. You can add server load balance virtual IPs from the CLI.

- Virtual IP *External IP Address/Range* entries or ranges cannot overlap with each other or with load balancing virtual server *Virtual Server IP* entries.
- A virtual IP *Mapped IP Address/Range* cannot be 0.0.0.0 or 255.255.255.255.
- A real server *IP* cannot be 0.0.0.0 or 255.255.255.255.
- If a static NAT virtual IP *External IP Address/Range* is 0.0.0.0, the *Mapped IP Address/Range* must be a single IP address.
- If a load balance virtual IP *External IP Address/Range* is 0.0.0.0, the *Mapped IP Address/Range* can be an address range.
- When port forwarding, the count of mapped port numbers and external port numbers must be the same. The web-based manager does this automatically but the CLI does not.
- Virtual IP and virtual server names must be different from firewall address or address group names.

## Monitoring load balancing

From the web-based manager you can go to *Firewall Objects > Monitor > Load Balance Monitor* to monitor the status of configured virtual servers and real server and start or stop the real servers. You can also use the `get test ipldb` command from the CLI to display similar information.

For each real server the monitor displays health status (up or down), active sessions, round trip time and the amount of bytes of data processed. From the monitor page you can also stop sending new sessions to any real server. When you select to stop sending sessions the FortiGate unit performs a graceful stop by continuing to send data for sessions that were established or persistent before you selected stop. However, no new sessions are started.

<b>Virtual Server</b>	The IP addresses of the existing virtual servers.
<b>Real Server</b>	The IP addresses of the existing real servers.
<b>Health Status</b>	Displays the health status according to the health check results for each real server. A green arrow means the server is up. A red arrow means the server is down.
<b>Mode</b>	The mode of the health check monitor. Can be active, standby, or disabled.
<b>Monitor Events</b>	Display each real server's up and down times.
<b>Active Sessions</b>	Display each real server's active sessions.
<b>RTT (ms)</b>	Displays the Round Trip Time (RTT) of each real server. By default, the RTT is "<1". This value will change only when ping monitoring is enabled on a real server.
<b>Bytes Processed</b>	Displays the traffic processed by each real server.
<b>Graceful Stop/Start</b>	Select to start or stop real servers. When stopping a server, the FortiGate unit will not accept new sessions but will wait for the active sessions to finish.

## Load balancing get command

The following get command is available to display testing and debug information for the FortiGate virtual server process:

```
get test vs <test-level_int>
```

Where <test-level\_int> can be:

- 3 to display the virtual server process id.
- 8 to display the virtual server log configuration.
- 30 to display the virtual server configuration statistics.
- 99 to restart the virtual server process.

## Load balancing diagnose commands

You can also use the following diagnose commands to view status information for load balancing virtual servers and real servers:

```
diagnose firewall vip realserver {down | flush | healthcheck | list |
up}
diagnose firewall vip virtual-server {filter | log | real-server |
session | stats}
```

For example, the following command lists and displays status information for all real servers:

```
diagnose firewall vip virtual-server real-server

vd root/0  vs vs/2  addr 10.31.101.30:80  status 1/1
conn: max 0  active 0  attempts 0  success 0  drop 0  fail 0

vd root/0  vs vs/2  addr 10.31.101.20:80  status 1/1
conn: max 0  active 0  attempts 0  success 0  drop 0  fail 0
```

Many of the diagnostic commands involve retrieving information about one or more virtual servers. To control which servers are queried you can define a filter:

```
diagnose firewall vip virtual-server filter <filter_str>
```

Where <filter\_str> can be:

- clear erase the current filter
- dst the destination address range to filter by
- dst-port the destination port range to filter by
- list display the current filter
- name the vip name to filter by
- negate negate the specified filter parameter
- src the source address range to filter by
- src-port the source port range to filter by
- vd index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

## Logging Diagnostics

The logging diagnostics provide information about two separate features:

```
diagnose firewall vip virtual-server log {console | filter}
```

Where

console {disable | enable} enables or disables displaying the event log messages generated by virtual server traffic on the console to simplify debugging.

filter sets a filter for the virtual server debug log

The filter option controls what entries the virtual server daemon will log to the console if `diagnose debug application vs level` is non-zero. The filtering can be done on source, destination, virtual-server name, virtual domain, and so on:

```
diagnose firewall vip virtual-server log filter <filter_str>
```

where <filter\_str> can be

- clear erase the current filter
- dst the destination address range to filter by
- dst-port the destination port range to filter by
- list display the current filter
- name the virtual-server name to filter by
- negate negate the specified filter parameter

`src` the source address range to filter by  
`src-port` the source port range to filter by  
`vd` index of virtual domain. -1 matches all  
The default filter is empty so no filtering is done.

## Real server diagnostics

Enter the following command to list all the real servers:

```
diag firewall vip virtual-server real-server list
```

In the following example there is only one virtual server called `slb` and it has two real-servers:

```
diag firewall vip virtual-server server
vd root/0  vs slb/2  addr 172.16.67.191:80  status 1/1
  conn: max 10  active 0  attempts 0  success 0  drop 0  fail 0
  http: available 0  total 0

vd root/0  vs slb/2  addr 172.16.67.192:80  status 1/1
  conn: max 10  active 1  attempts 4  success 4  drop 0  fail 0
  http: available 1  total 1
```

The `status` indicates the administrative and operational status of the real-server.

`max` indicates that the real-server will only allow 10 concurrent connections.

`active` is the number of current connections to the server `attempts` is the total number of connections attempted `success` is the total number of connections that were successful.

`drop` is the total number of connections that were dropped because the active count hit max.

`fail` is the total number of connections that failed to complete due to some internal problem (for example, lack of memory).

If the virtual server has HTTP multiplexing enabled then the HTTP section indicates how many established connections to the real-server are available to service a HTTP request and also the total number of connections.

## Basic load balancing configuration example

This section describes the steps required to configure the load balancing configuration shown in [Figure 290](#). In this configuration a FortiGate-51B unit is load balancing HTTP traffic from the Internet to three HTTP servers on the Internal network. HTTP sessions are accepted at the `wan1` interface with destination IP address 172.20.120.121 on TCP port 8080 and forwarded from the internal interface to the web servers. When forwarded the destination address of the sessions is translated to the IP address of one of the web servers.

The load balancing configuration also includes session persistence using HTTP cookies, round-robin load balancing, and TCP health monitoring for the real servers. Ping health monitoring consists of the FortiGate unit using ICMP ping to make sure the web servers can respond to network traffic.

**Figure 290:**Virtual server and real servers setup

#### To configure the example load balancing configuration - general configuration steps

- 1 Add a load balance ping health check monitor  
A ping health check monitor causes the FortiGate unit to ping the real servers every 10 seconds. If one of the servers does not respond within 2 seconds, the FortiGate unit will retry the ping 3 times before assuming that the HTTP server is not responding.
- 2 Add a load balance virtual server.
- 3 Add the three load balance real servers. Include the virtual server in each real server configuration.
- 4 Add a security policy that includes the load balance virtual server as the destination address.

#### To configure the example load balancing configuration - web-based manager

- 1 Go to go to *Firewall Objects > Load Balance > Health Check* and add the following health check monitor.

<b>Name</b>	Ping-mon-1
<b>Type</b>	Ping
<b>Interval</b>	10 seconds
<b>Timeout</b>	2 seconds
<b>Retry</b>	3

- 2 Go to *Firewall Objects > Load Balance > Virtual Server* and add virtual server that accepts the traffic to be load balanced.

<b>Name</b>	Vserver-HTTP-1
<b>Type</b>	HTTP
<b>Interface</b>	wan1
<b>Virtual Server IP</b>	172.20.120.121
<b>Virtual Server Port</b>	8080
<b>Load Balance Method</b>	Round Robin
<b>Persistence</b>	HTTP Cookie
<b>HTTP Multiplexing</b>	Do not select
<b>Health Check</b>	Move Ping-mon-1 to the Selected list.

- 3 Go to go to *Firewall Objects > Load Balance > Real Server* and add the real servers.

<b>Virtual Server</b>	Vserver-HTTP-1
<b>IP Address</b>	10.31.101.30
<b>Port</b>	80
<b>Weight</b>	n/a
<b>Max Connections</b>	0
<b>Mode</b>	Active
<b>Virtual Server</b>	Vserver-HTTP-1
<b>IP Address</b>	10.31.101.40
<b>Port</b>	80
<b>Weight</b>	n/a
<b>Max Connections</b>	0
<b>Mode</b>	Active
<b>Virtual Server</b>	Vserver-HTTP-1
<b>IP Address</b>	10.31.101.50
<b>Port</b>	80
<b>Weight</b>	n/a

<b>Max Connections</b>	0
<b>Mode</b>	Active

- 4 Go to *Policy > Policy > Policy* and add a wan1 to internal security policy that includes the virtual server. This policy also applies an Antivirus profile to the load balanced sessions.

<b>Policy Type</b>	Firewall
<b>Policy Subtype</b>	Address
<b>Incoming Interface</b>	wan1
<b>Source Address</b>	all
<b>Outgoing Interface</b>	internal
<b>Destination Address</b>	Vserver-HTTP-1
<b>Schedule</b>	always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Select this option and select <i>Use Destination Interface Address</i> .
<b>Use Standard UTM Profiles</b>	Select
<b>Antivirus</b>	Turn ON and select an Antivirus profile.
<b>UTM Proxy Options</b>	Select a profile.

5. Select OK.

#### To configure the example load balancing configuration- CLI

- 1 Use the following command to add a Ping health check monitor.

```
config firewall ldb-monitor
edit ping-mon-1
set type ping
set interval 10
set timeout 2
set retry 3
end
```

- 2 Use the following command to add the virtual server that accepts HTTP sessions on port 8080 at the wan1 interface and load balances the traffic to three real servers.

```
config firewall vip
    edit Vserver-HTTP-1
        set type server-load-balance
        set server-type http
        set ldb-method round-robin
        set extip 172.20.120.30
        set extintf wan1
        set extport 8080
        set persistence http-cookie
        set monitor tcp-mon-1
        config realservers
            edit 1
                set ip 10.31.101.30
                set port 80
            next
            edit 2
                set ip 10.31.101.40
                set port 80
            end
        end
    end
```

- 3 Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
    edit 0
        set srcintf wan1
        set srcaddr all
        set dstintf internal
        set dstaddr Vserver-HTTP-1
        set action accept
        set schedule always
        set service ALL
        set nat enable
        set utm-status enable
        set profile-protocol-options default
        set av-profile scan
    end
```

## HTTP and HTTPS load balancing, multiplexing, and persistence

In a firewall load balancing virtual server configuration, you can select HTTP to load balance only HTTP sessions. The virtual server will load balance HTTP sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. The default virtual server port for HTTP load balancing is 80, but you can change this to any port number. Similarly for HTTPS load balancing, set the virtual server type to HTTPS and then select the interface, virtual server IP, and virtual server port that matches the HTTPS traffic to be load balanced. Usually HTTPS traffic uses port 443.

You can also configure load balancing to offload SSL processing for HTTPS and SSL traffic. See [“SSL offloading” on page 1903](#) for more information.

## HTTP and HTTPS multiplexing

For both HTTP and HTTPS load balancing you can multiplex HTTP requests and responses over a single TCP connection. HTTP multiplexing is a performance saving feature of HTTP/1.1 compliant web servers that provides the ability to pipeline many unrelated HTTP or HTTPS requests on the same connection. This allows a single HTTPD process on the server to interleave and serve multiple requests. The result is fewer idle sessions on the web server so server resources are used more efficiently. HTTP multiplexing can take multiple separate inbound sessions and multiplex them over the same internal session. This may reduce the load on the backend server and increase the overall performance.

HTTP multiplexing may improve performance in some cases. For example, if users web browsers are only compatible with HTTP 1.0. HTTP multiplexing can also improve performance between a web server and the FortiGate unit if the FortiGate unit is performing SSL acceleration. However, in most cases HTTP multiplexing should only be used if enabling it leads to a measurable improvement in performance.

To enable HTTP multiplexing from the web-based manager, select multiplex HTTP requests/responses over a single TCP connection. To enable HTTP multiplexing from the CLI enable the `http-multiplex` option.

## Preserving the client IP address

Select preserve client IP from the web-based manager or enable the `http-ip-header` option from the CLI to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful in an HTTP multiplexing configuration if you want log messages on the real servers to the client's original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit.

## HTTP and HTTPS persistence

Configure load balancing persistence for HTTP or HTTPS to make sure that a user is connected to the same server every time they make a request that is part of the same session. HTTP cookie persistence uses injected cookies to enable persistence.

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the *Load Balance Method*. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server.

The following example shows how to enable cookie persistence and set the cookie domain to `.example.org`.

```
config firewall vip
  edit HTTP_Load_Balance
    set type server-load-balance
    set server-type http
    set extport 8080
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
    config realservers
      edit 1
        set ip 10.10.10.1
        set port 80
      next
      edit 2
        set ip 10.10.10.2
        set port 80
      next
      edit 3
        set ip 10.10.10.3
        set port 80
    end
  end
end
```

## How HTTP cookie persistence options work

The following options are available for the `config firewall vip` command when `type` is set to `server-load-balance`, `server-type` is set to `http` or `https` and `persistence` is set to `http-cookie`:

```
http-cookie-domain-from-host
http-cookie-domain
http-cookie-path
http-cookie-generation
http-cookie-age
http-cookie-share
https-cookie-share
```

When HTTP cookie persistence is enabled the FortiGate unit inserts a header of the following form into each HTTP response unless the corresponding HTTP request already contains a `FGTServer` cookie:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;
Version=1; Max-Age=3600
```

The value of the `FGTServer` cookie encodes the server that traffic should be directed to. The value is encoded so as to not leak information about the internal network.

Enable `http-cookie-domain-from-host` to extract the cookie domain from the `host` header in the HTTP request. For example, to restrict the cookie to `.server.com`, enter:

The generated cookies could have the following form if the *Host:* header contains *exhost.com*:

```
Set-Cookie: FGTSerVer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;  
Version=1; Domain=.exhost.com; Max-Age=3600
```

For more information, see [“HTTP host-based load balancing” on page 1901](#).

Use `http-cookie-domain` to restrict the domain that the cookie should apply to. For example, to restrict the cookie to `.server.com`, enter:

```
set http-cookie-domain .server.com
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTSerVer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;  
Version=1; Domain=.server.com; Max-Age=3600
```

Use `http-cookie-path` to limit the cookies to a particular path. For example, to limit cookies to the path `/sales`, enter:

```
set http-cookie-path /sales
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTSerVer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;  
Version=1; Domain=.server.com; Path=/sales; Max-Age=3600
```

Use `http-cookie-age` to change how long the browser caches the cookie. You can enter an age in minutes or set the age to 0 to make the browser keep the cookie indefinitely:

```
set http-cookie-age 0
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTSerVer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;  
Version=1; Domain=.server.com; Path=/sales
```

Use `http-cookie-generation` to invalidate all cookies that have already been generated. The exact value of the generation is not important, only that it is different from any generation that has already been used for cookies in this domain. The simplest approach is to increment the generation by one each time invalidation is required. Since the default is 0, enter the following to invalidate all existing cookies:

```
set http-cookie-generation 1
```

Use `http-cookie-share {disable | same-ip}` to control the sharing of cookies across virtual servers in the same virtual domain. The default setting `same-ip` means that any `FGTSerVer` cookie generated by one virtual server can be used by another virtual server in the same virtual domain. For example, if you have an application that starts on HTTP and then changes to HTTPS and you want to make sure that the same server is used for the HTTP and HTTPS traffic then you can create two virtual servers, one for port 80 (for HTTP) and one for port 443 (for HTTPS). As long as you add the same real servers to both of these virtual servers (and as long as both virtual servers have the same number of real servers with the same IP addresses), then cookies generated by accessing the HTTP server are reused when the application changes to the HTTPS server.

If for any reason you do not want this sharing to occur then select `disable` to make sure that a cookie generated for a virtual server cannot be used by other virtual servers.

Use `https-cookie-secure` to enable or disable using secure cookies. Secure cookies are disabled by default because secure cookies can interfere with cookie sharing across HTTP and HTTPS virtual servers. If enabled, then the `Secure` tag is added to the cookie inserted by the FortiGate unit:

```
Set-Cookie: FGTSerVer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;  
Version=1; Max-Age=3600; Secure
```

## HTTP host-based load balancing

When configuring HTTP or HTTPS load balancing you can select HTTP host load balancing to load balance HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server. HTTP 1.1 includes the concept of a virtual server which allows a HTTP or HTTPS server with a single external IP address to serve requests for multiple DNS domains by using the mandatory `Host:` header in a HTTP request to indicate which DNS domain the request is destined for.

FortiOS can load-balance HTTP and HTTPS connections among multiple real servers using the `Host:` header to guide the connection to the correct real server. The host load balancing method allows a real server to specify a `http-host` attribute which is the domain name of the traffic for that real server. Each real server can only specify a single domain name. The same domain name can appear in more than one real server but only the first one that is up will be used, any others are purely for redundancy. If the `Host:` header contains a domain that does not match any `http-host` entry then the connection will be dropped. A real server with no `http-host` can be matched by any `Host:` domain.

For example, consider a FortiGate unit that is load-balancing traffic to three real servers. Traffic for `www.example1.com` should go to 192.168.2.1, traffic for `www.example2.com` should go to 192.168.2.2 and traffic to any other domain should go to 192.168.2.3. To enable this configuration you would add a virtual server and set the load balance method to HTTP host. Then you would add three real servers and set the HTTP host of the real server with IP address 192.168.2.1 to `www.example1.com`, the HTTP host of the real server with IP address 192.168.2.2 to `www.example2.com` and you would not specify an HTTP host for the third real server.

The configuration of a virtual IP to achieve this result would be:

```
config firewall vip
  edit "http-host-ldb"
    set type server-load-balance
    set extip 172.16.67.195
    set extintf "lan"
    set server-type http
    set ldb-method http-host
    set extport 80
    config realservers
      edit 1
        set http-host "www.example1.com"
        set ip 192.168.2.1
        set port 80
      next
      edit 2
        set http-host "www.example2.com"
        set ip 192.168.2.2
        set port 80
      next
      edit 3
        set ip 192.168.2.3
        set port 80
      next
    end
  end
end
```

## Host load balancing and HTTP cookie persistence

In an HTTP host-based load balancing configuration with HTTP cookie persistence enabled you can optionally configure cookie persistence to use the domain set in the host header as the cookie domain. You can do this by enabling the `http-cookie-domain-from-host` option, for example:

```
config firewall vip
  edit "http-host-ldb"
    set type server-load-balance
    set extip 172.16.67.195
    set extintf "lan"
    set server-type http
    set ldb-method http-host
    set extport 80
    set persistence http-cookie
    set http-cookie-domain-from-host enable
  config realservers
    edit 1
      set http-host "www.example1.com"
      set ip 192.168.2.1
      set port 80
    next
    edit 2
      set http-host "www.example2.com"
      set ip 192.168.2.2
      set port 80
    next
    edit 3
      set ip 192.168.2.3
      set port 80
    next
  end
end
```

## SSL/TLS load balancing

In a firewall load balancing virtual server configuration, you can select SSL to load balance only SSL and TLS sessions. The virtual server will load balance SSL and TLS sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. Change this port to match the destination port of the sessions to be load balanced.

For SSL load balancing you can also set persistence to SSL session ID. Persistence is achieved by the FortiGate unit sending all sessions with the same SSL session ID to the same real server. When you configure persistence, the FortiGate unit load balances a new session to a real server according to the *Load Balance Method*. If the session has an SSL session ID, the FortiGate unit sends all subsequent sessions with the same SSL session ID to the same real server.

## SSL offloading

Use SSL offloading to accelerate clients' SSL or HTTPS connections to real servers by using the FortiGate unit to perform SSL operations (offloading them from the real servers using the FortiGate unit's SSL acceleration hardware). FortiGate units can offload SSL 3.0 and TLS 1.0. SSL offloading is available on FortiGate units that support SSL acceleration.

To configure SSL offloading from the web-based manager go to *Firewall Objects > Load Balance > Virtual Server*. Add a virtual server and set the type to HTTPS or SSL and select the SSL offloading type (Client <-> FortiGate or Client <-> FortiGate <-> Server).

Select Client <-> FortiGate to apply hardware accelerated SSL processing only to the part of the connection between the client and the FortiGate unit. This mode is called half mode SSL offloading. The segment between the FortiGate unit and the server will use clear text communications. This results in best performance, but cannot be used in failover configurations where the failover path does not have an SSL accelerator.

Select Client <-> FortiGate <-> Server to apply hardware accelerated SSL processing to both parts of the connection: the segment between client and the FortiGate unit, and the segment between the FortiGate unit and the server. This mode is called full mode SSL offloading. The segment between the FortiGate unit and the server will use encrypted communications, but the handshakes will be abbreviated. This results in performance which is less than the other option, but still improved over communications without SSL acceleration, and can be used in failover configurations where the failover path does not have an SSL accelerator. If the server is already configured to use SSL, this also enables SSL acceleration without requiring changes to the server's configuration.

**Figure 291:**SSL Offloading modes

Configuring SSL offloading also requires selecting a certificate to use for the SSL offloading sessions. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

The following CLI command shows an example half mode HTTPS SSL offloading configuration. In the example the `ssl-mode` option sets the SSL offload mode to `half` (which is the default mode).

```
config firewall vip
  edit Vserver-ssl-offload
    set type server-load-balance
    set server-type https
    set ldb-method round-robin
    set extip 172.20.120.30
    set extintf wan1
    set extport 443
    set persistence ssl-session-id
    set ssl-mode half
    set ssl-certificate my-cert
    set monitor t cp-mon-1
  config realservers
    edit 1
      set ip 10.31.101.30
      set port 443
    next
    edit 2
      set ip 10.31.101.40
      set port 443
  end
end
```

### Additional SSL load balancing options

The following SSL load balancing and SSL offloading options are only available from the CLI:

```
ssl-client-session-state-max <sessionstates_int>
```

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the client and the FortiGate unit.

```
ssl-client-session-state-timeout <timeout_int>
```

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the client and the FortiGate unit.

```
ssl-client-session-state-type {both | client | disable | time}
```

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the client and the FortiGate unit.

- **both:** Select to expire SSL session states when either `ssl-client-session-state-max` or `ssl-client-session-state-timeout` is exceeded, regardless of which occurs first.
- **count:** Select to expire SSL session states when `ssl-client-session-state-max` is exceeded.
- **disable:** Select to keep no SSL session states.
- **time:** Select to expire SSL session states when `ssl-client-session-state-timeout` is exceeded.

```
ssl-dh-bits <bits_int>
```

Enter the number of bits of the prime number used in the Diffie-Hellman exchange for RSA encryption of the SSL connection. Larger prime numbers are associated with greater cryptographic strength.

```
ssl-http-location-conversion {enable | disable}
```

Select to replace `http` with `https` in the reply's `Location` HTTP header field. For example, in the reply, `Location: http://example.com/` would be converted to `Location: https://example.com/`

```
ssl-http-match-host {enable | disable}
```

Select to apply `Location` conversion to the reply's HTTP header only if the host name portion of `Location` matches the request's `Host` field, or, if the `Host` field does not exist, the host name portion of the request's URI. If disabled, conversion occurs regardless of whether the host names in the request and the reply match.

For example, if host matching is enabled, and a request contains `Host: example.com` and the reply contains `Location: http://example.cc/`, the `Location` field does not match the host of the original request and the reply's `Location` field remains unchanged. If the reply contains `Location: http://example.com/`, however, then the FortiGate unit detects the matching host name and converts the reply field to `Location: https://example.com/`.

This option appears only if `ssl-http-location-conversion` is `enable`.

```
ssl-max-version {ssl-3.0 | tls-1.0}
```

Enter the maximum version of SSL/TLS to accept in negotiation.

```
ssl-min-version {ssl-3.0 | tls-1.0}
```

Enter the minimum version of SSL/TLS to accept in negotiation.

```
ssl-send-empty-frags {enable | disable}
```

Select to precede the record with empty fragments to thwart attacks on CBC IV. You might disable this option if SSL acceleration will be used with an old or buggy SSL implementation which cannot properly handle empty fragments.

```
ssl-server-session-state-max <sessionstates_int>
```

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the server and the FortiGate unit.

```
ssl-server-session-state-timeout <timeout_int>
```

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if `ssl-mode` is `full`.

```
ssl-server-session-state-type {both | count | disable | time}
```

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if `ssl-mode` is `full`.

- **both:** Select to expire SSL session states when either `ssl-server-session-state-max` or `ssl-server-session-state-timeout` is exceeded, regardless of which occurs first.
- **count:** Select to expire SSL session states when `ssl-server-session-state-max` is exceeded.
- **disable:** Select to keep no SSL session states.
- **time:** Select to expire SSL session states when `ssl-server-session-state-timeout` is exceeded.

## SSL offloading support or Internet Explorer 6

In some cases the Internet Explorer 6 web browser may be able to access real servers. To resolve this issue, disable the `ssl-send-empty-frags` option:

```
config firewall vip
edit vip_name
set ssl-send-empty-frags disable
end
```

You can disable this option if SSL acceleration will be used with an old or buggy SSL implementation that cannot properly handle empty fragments.

## Disabling SSL/TLS re-negotiation

The vulnerability [CVE-2009-3555](#) affects all SSL/TLS servers that support re-negotiation. FortiOS when configured for SSL/TLS offloading is operating as a SSL/TLS server. The IETF is working on a TLS protocol change that will fix the problem identified by CVE-2009-3555 while still supporting re-negotiation. Until that protocol change is available, you can use the `ssl-client-renegotiation` option to disable support for SSL/TLS re-negotiation. The default value of this option is `allow`, which allows an SSL client to renegotiate. You can change the setting to `deny` to abort any attempts by an SSL client to renegotiate. If you select `deny` as soon as a `ClientHello` message indicating a re-negotiation is received from the client FortiOS terminates the TCP connection.

Since SSL offloading does not support requesting client certificates the only circumstance in which a re-negotiation is required is when more than  $2^{32}$  bytes of data are exchanged over a single handshake. If you are sure that this volume of traffic will not occur then you can disable re-negotiation and avoid any possibility of the attack described in CVE-2009-3555.

The re-negotiation behavior can be tested using OpenSSL. The OpenSSL `s_client` application has the feature that the user can request that it do renegotiation by typing "R". For example, the following shows a successful re-negotiation against a FortiGate unit configured with a VIP for 192.168.2.100:443:

```
$ openssl s_client -connect 192.168.2.100:443

```

## IP, TCP, and UDP load balancing

You can load balance all IP, TCP or UDP sessions accepted by the security policy that includes a load balancing virtual server with the type set to IP, TCP, or UDP. Traffic with destination IP and port that matches the virtual server IP and port is load balanced. For these protocol-level load balancing virtual servers you can select a load balance method and add real servers and health checking. However, you can't configure persistence, HTTP multiplexing and SSL offloading.

# Load balancing configuration examples

This chapter includes the following examples:

- Example: HTTP load balancing to three real web servers
- Example: Basic IP load balancing configuration
- Example: Adding a server load balance port forwarding virtual IP
- Example: Weighted load balancing configuration
- Example: HTTP and HTTPS persistence configuration

## Example: HTTP load balancing to three real web servers

In this example, the virtual web server IP address 192.168.37.4 on the Internet, is mapped to three real web servers connected to the FortiGate unit dmz1 interface. The real servers have IP addresses 10.10.123.42, 10.10.123.43, and 10.10.123.44. The virtual server uses the *First Alive* load balancing method. The configuration also includes an HTTP health check monitor that includes a URL used by the FortiGate unit for get requests to monitor the health of the real servers.

Connections to the virtual web server at IP address 192.168.37.4 from the Internet are translated and load balanced to the real servers by the FortiGate unit. First alive load balancing directs all sessions to the first real server. The computers on the Internet are unaware of this translation and load balancing and see a single virtual server at IP address 192.168.37.4 rather than the three real servers behind the FortiGate unit.

**Figure 292:**Virtual server configuration example

## Web-based manager configuration

Use the following procedures to configure this load balancing setup from the web-based manager.

### To add an HTTP health check monitor

In this example, the HTTP health check monitor includes the *URL* “/index.html” and the *Matched Phrase* “Fortinet products”.

1. Go to *Firewall Objects > Load Balance > Health Check*.
2. Select *Create New*.
3. Add an HTTP health check monitor that sends get requests to `http://<real_server_IP_address>/index.html` and searches the returned web page for the phrase “Fortinet products”.

<b>Name</b>	HTTP_health_chk_1
<b>Type</b>	HTTP
<b>Port</b>	80
<b>URL</b>	/index.html
<b>Matched Content</b>	Fortinet products
<b>Interval</b>	10 seconds
<b>Timeout</b>	2 seconds
<b>Retry</b>	3

4. Select *OK*.

### To add the HTTP virtual server

1. Go to *Firewall Objects > Load Balance > Virtual Server*.
2. Select *Create New*.
3. Add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

<b>Name</b>	Load_Bal_VS1
<b>Type</b>	HTTP
<b>Interface</b>	wan1

<b>Virtual Server IP</b>	192.168.37.4  The public IP address of the web server.  The virtual server IP address is usually a static IP address obtained from your ISP for your web server. This address must be a unique IP address that is not used by another host and cannot be the same as the IP address of the external interface the virtual IP will be using. However, the external IP address must be routed to the selected interface. The virtual IP address and the external IP address can be on different subnets. When you add the virtual IP, the external interface responds to ARP requests for the external IP address.
<b>Virtual Server Port</b>	80
<b>Load Balance Method</b>	First Alive
<b>Persistence</b>	HTTP cookie
<b>HTTP Multiplexing</b>	Select.  The FortiGate unit multiplexes multiple client into a few connections between the FortiGate unit and each real HTTP server. This can improve performance by reducing server overhead associated with establishing multiple connections.
<b>Preserve Client IP</b>	Select  The FortiGate unit preserves the IP address of the client in the X-Forwarded-For HTTP header.
<b>Health Check</b>	Move the HTTP_health_chk_1 health check monitor to the <i>Selected</i> list.

4. Select *OK*.

#### **To add the real servers and associate them with the virtual server**

1. Go to *Firewall Objects > Load Balance > Real Server*.
2. Select *Create New*.

3. Configure three real servers that include the virtual server Load\_Bal\_VS1. Each real server must include the IP address of a real server on the internal network.

Configuration for the first real server.

<b>Virtual Server</b>	Load_Bal_VS1
<b>IP Address</b>	10.10.10.42
<b>Port</b>	80
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0  Setting <i>Maximum Connections</i> to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses <i>First Alive</i> load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the <i>Maximum Connections</i> is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the second real server.

<b>Virtual Server</b>	Load_Bal_VS1
<b>IP Address</b>	10.10.10.43
<b>Port</b>	80
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0  Setting <i>Maximum Connections</i> to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses <i>First Alive</i> load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the <i>Maximum Connections</i> is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the third real server.

<b>Virtual Server</b>	Load_Bal_VS1
<b>IP Address</b>	10.10.10.44
<b>Port</b>	80

<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0
	Setting <i>Maximum Connections</i> to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses <i>First Alive</i> load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the <i>Maximum Connections</i> is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

### To add the virtual server to a security policy

Add a wan1 to dmz1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to *Policy > Policy > Policy*.
2. Select *Create New*.
3. Configure the security policy:

<b>Policy Type</b>	Firewall
<b>Policy Subtype</b>	Address
<b>Incoming Interface</b>	wan1
<b>Source Address</b>	all (or a more specific address)
<b>Outgoing Interface</b>	dmz1
<b>Destination Address</b>	Load_Bal_VS1
<b>Schedule</b>	always
<b>Service</b>	HTTP
<b>Action</b>	ACCEPT
<b>Log Allowed Traffic</b>	Select to log virtual server traffic
<b>Enable NAT</b>	Select this option and select <i>Use Destination Interface Address</i> .

4. Select other security policy options as required.
5. Select *OK*.

## CLI configuration

Use the following procedure to configure this load balancing setup from the CLI.

## To configure HTTP load balancing

1. Use the following command to add an HTTP health check monitor that sends get requests to `http://<real_server_IP_address>/index.html` and searches the returned web page for the phrase "Fortinet products".

```
config firewall ldb-monitor
  edit HTTP_health_chk_1
    set type http
    set port 80
    set http-get /index.html
    set http-match "Fortinet products"
    set interval 10
    set timeout 2
    set retry 3
  end
```

2. Use the following command to add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

```
config firewall vip
  edit Load-Bal_VS1
    set type server-load-balance
    set server-type http
    set ldb-method first-alive
    set http-multiplex enable
    set http-ip-header enable
    set extip 192.168.37.4
    set extintf wan1
    set extport 80
    set persistence http-cookie
    set monitor HTTP_health_chk_1
    config realservers
      edit 1
        set ip 10.10.10.42
        set port 80
      next
      edit 2
        set ip 10.10.10.43
        set port 80
      next
      edit 3
        set ip 10.10.10.44
        set port 80
    end
  end
```

3. Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
  edit 0
    set srcintf wan1
    set srcaddr all
    set dstintf dmz1
    set dstaddr Load-Bal_VS1
    set action accept
    set schedule always
    set service ALL
    set nat enable
  end
```

Configure other security policy settings as required.

## Example: Basic IP load balancing configuration

This example shows how to add a server load balancing virtual IP that load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3. The default weight is 1 and does not have to be changed for the first real server.

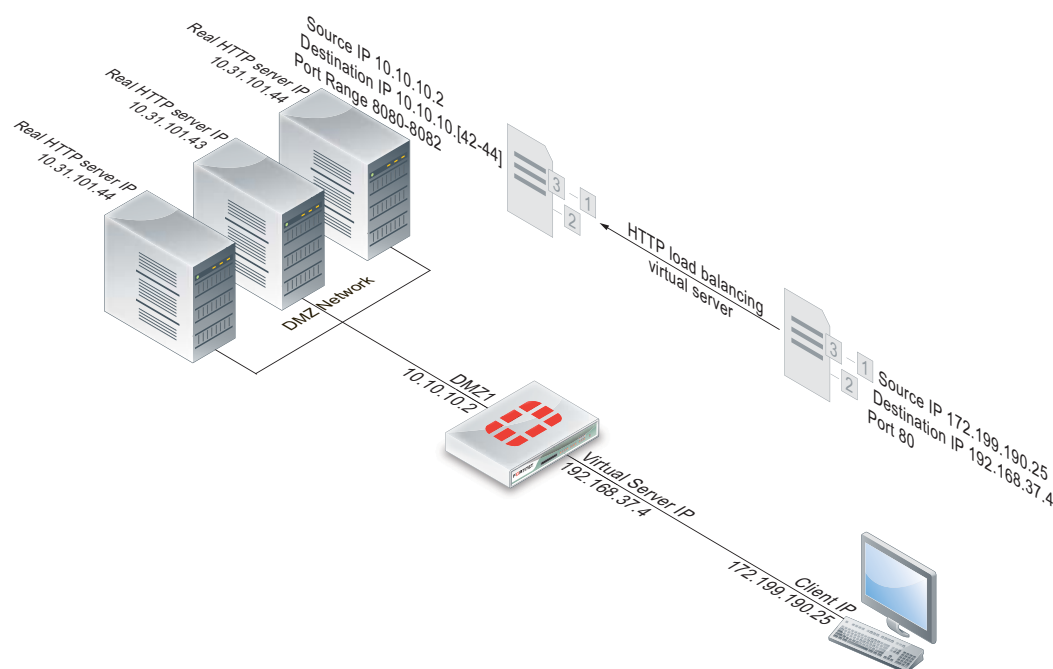

```
config firewall vip
  edit All_Load_Balance
    set type server-load-balance
    set server-type ip
    set extintf port2
    set extip 192.168.20.20
    set ldb-method weighted
    config realservers
      edit 1
        set ip 10.10.10.1
      next
      edit 2
        set ip 10.10.10.2
        set weight 2
      next
      edit 3
        set ip 10.10.10.3
        set weight 3
      end
    end
  end
```

## Example: Adding a server load balance port forwarding virtual IP

This example is the same as the example described in [“Example: HTTP load balancing to three real web servers” on page 1911](#) except that each real server accepts HTTP connections on a

different port number. The first real server accepts connections on port 8080, the second on port 8081, and the third on 8082.

**Figure 293:**Server load balance virtual IP port forwarding

To complete this configuration, all of the steps would be the same as in [“Example: HTTP load balancing to three real web servers”](#) on page 1911 except for configuring the real servers.

#### To add the real servers and associate them with the virtual server

Use the following steps to configure the FortiGate unit to port forward HTTP packets to the three real servers on ports 8080, 8081, and 8082.

1. Go to *Firewall Objects > Load Balance > Real Server*.
2. Select *Create New*.
3. Configure three real servers that include the virtual server Load\_Bal\_VS1. Each real server must include the IP address of a real server on the internal network and have a different port number.

Configuration for the first real server.

<b>Virtual Server</b>	Load_Bal_VS1
<b>IP</b>	10.10.10.42
<b>Port</b>	8080
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

Configuration for the second real server.

<b>Virtual Server</b>	Load_Bal_VS1
<b>IP</b>	10.10.10.43
<b>Port</b>	8081
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

Configuration for the third real server.

<b>Virtual Server</b>	Load_Bal_VS1
<b>IP</b>	10.10.10.44
<b>Port</b>	8082
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

## Example: Weighted load balancing configuration

This example shows how to using firewall load balancing to load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3.

This configuration does not include an health check monitor.

## Web-based manager configuration

Use the following procedures to configure this load balancing setup from the web-based manager.

### To add the HTTP virtual server

1. Go to *Firewall Objects > Load Balance > Virtual Server*.
2. Select *Create New*.

3. Add an IP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate port2 interface is connected to the Internet.

<b>Name</b>	HTTP_weghted_LB
<b>Type</b>	IP
<b>Interface</b>	port2
<b>Virtual Server IP</b>	192.168.20.20
<b>Load Balance Method</b>	Weighted

All other virtual server settings are not required or cannot be changed.

4. Select **OK**.

#### To add the real servers and associate them with the virtual server

1. Go to *Firewall Objects > Load Balance > Real Server*.
2. Select *Create New*.
3. Configure three real servers that include the virtual server *All\_Load \_Balance*. Because the *Load Balancing Method* is *Weighted*, each real server includes a weight. Servers with a greater weight receive a greater proportion of forwarded connections,  
Configuration for the first real server.

<b>Virtual Server</b>	HTTP_weghted_LB
<b>IP Address</b>	10.10.10.1
<b>Port</b>	Cannot be configured because the virtual server is an IP server.
<b>Weight</b>	1
<b>Maximum Connections</b>	0  Setting <i>Maximum Connections</i> to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses <i>First Alive</i> load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the <i>Maximum Connections</i> is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the second real server.

<b>Virtual Server</b>	HTTP_weghted_LB
<b>IP Address</b>	10.10.10.2
<b>Port</b>	Cannot be configured because the virtual server is an IP server.
<b>Weight</b>	2
<b>Maximum Connections</b>	0  Setting <i>Maximum Connections</i> to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses <i>First Alive</i> load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the <i>Maximum Connections</i> is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the third real server.

<b>Virtual Server</b>	HTTP_weghted_LB
<b>IP Address</b>	10.10.10.3
<b>Port</b>	Cannot be configured because the virtual server is an IP server.
<b>Weight</b>	3
<b>Maximum Connections</b>	0  Setting <i>Maximum Connections</i> to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses <i>First Alive</i> load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the <i>Maximum Connections</i> is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

### To add the virtual server to a security policy

Add a prot2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to *Policy > Policy > Policy*.
2. Select *Create New*.
3. Configure the security policy:

<b>Policy Type</b>	Firewall
<b>Policy Subtype</b>	Address
<b>Incoming Interface</b>	port2
<b>Source Address</b>	all (or a more specific address)

<b>Outgoing Interface</b>	port1
<b>Destination Address</b>	HTTP_weghted_LB
<b>Schedule</b>	always
<b>Service</b>	ALL
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Select this option and select <i>Use Destination Interface Address</i> .

4. Select other security policy options as required.
5. Select *OK*.

## CLI configuration

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`. The default weight is 1 and does not have to be changed for the first real server.

Use the following command to add the virtual server and the three weighted real servers.

```
config firewall vip
  edit HTTP_weghted_LB
    set type server-load-balance
    set server-type ip
    set extintf port2
    set extip 192.168.20.20
    set ldb-method weighted
    config realservers
      edit 1
        set ip 10.10.10.1
      next
      edit 2
        set ip 10.10.10.2
        set weight 2
      next
      edit 3
        set ip 10.10.10.3
        set weight 3
    end
  end
```

## Example: HTTP and HTTPS persistence configuration

This example shows how to add a virtual server named *Http\_Load\_Balance* that load balances HTTP traffic using port 80 and a second virtual server named *Https\_Load\_Balance* that load balances HTTPS traffic using port 443. The Internet is connected to port2 and the virtual IP address of the virtual server is 192.168.20.20. Both server load balancing virtual IPs load balance sessions to the same three real servers with IP addresses 10.10.10.2, 10.10.10.2, and 10.10.10.3. The real servers provide HTTP and HTTPS services.

For both virtual servers, persistence is set to *HTTP Cookie* to enable HTTP cookie persistence.

**To add the HTTP and HTTPS virtual servers**

1. Go to *Firewall Objects > Load Balance > Virtual Server*.
2. Add the HTTP virtual server that includes HTTP Cookie persistence.

<b>Name</b>	HTTP_Load_Balance
<b>Type</b>	HTTP
<b>Interface</b>	port2
<b>Virtual Server IP</b>	192.168.20.20
<b>Virtual Server Port</b>	80  In this example the virtual server uses port 8080 for HTTP sessions instead of port 80.
<b>Load Balance Method</b>	Static
<b>Persistence</b>	HTTP cookie

3. Select *OK*.
4. Select *Create New*.
5. Add the HTTPS virtual server that also includes HTTP Cookie persistence.

<b>Name</b>	HTTPS_Load_Balance
<b>Type</b>	HTTPS
<b>Interface</b>	port2
<b>Virtual Server IP</b>	192.168.20.20
<b>Virtual Server Port</b>	443
<b>Load Balance Method</b>	Static
<b>Persistence</b>	HTTP cookie

6. Select *OK*.

**To add the real servers and associate them with the virtual servers**

1. Go to *Firewall Objects > Load Balance > Real Server*.
2. Select *Create New*.

3. Configure three real servers for HTTP that include the virtual server HTTP\_Load\_Balance. Configuration for the first HTTP real server.

<b>Virtual Server</b>	HTTP_Load_Balance
<b>IP Address</b>	10.10.10.1
<b>Port</b>	80
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

Configuration for the second HTTP real server.

<b>Virtual Server</b>	HTTP_Load_Balance
<b>IP Address</b>	10.10.10.2
<b>Port</b>	80
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

Configuration for the third HTTP real server.

<b>Virtual Server</b>	HTTP_Load_Balance
<b>IP Address</b>	10.10.10.3
<b>Port</b>	80
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

4. Configure three real servers for HTTPS that include the virtual server HTTPS\_Load\_Balance. Configuration for the first HTTPS real server.

<b>Virtual Server</b>	HTTP_Load_Balance
<b>IP Address</b>	10.10.10.1
<b>Port</b>	443
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

Configuration for the second HTTPS real server.

<b>Virtual Server</b>	HTTP_Load_Balance
<b>IP Address</b>	10.10.10.2
<b>Port</b>	443
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

Configuration for the third HTTPS real server.

<b>Virtual Server</b>	HTTPS_Load_Balance
<b>IP Address</b>	10.10.10.3
<b>Port</b>	443
<b>Weight</b>	Cannot be configured because the virtual server does not include weighted load balancing.
<b>Maximum Connections</b>	0

### To add the virtual servers to security policies

Add a port2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to *Policy > Policy > Policy*.
2. Select *Create New*.
3. Configure the HTTP security policy:

<b>Policy Type</b>	Firewall
<b>Policy Subtype</b>	Address
<b>Incoming Interface</b>	port2

<b>Source Address</b>	all
<b>Outgoing Interface</b>	port1
<b>Destination Address</b>	HTTP_Load_Balance
<b>Schedule</b>	always
<b>Service</b>	HTTP
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Select this option and select <i>Use Destination Interface Address</i> .

4. Select other security policy options as required.
5. Select *OK*.
6. Select *Create New*.
7. Configure the HTTP security policy:

<b>Policy Type</b>	Firewall
<b>Policy Subtype</b>	Address
<b>Incoming Interface</b>	port2
<b>Source Address</b>	all
<b>Outgoing Interface</b>	port1
<b>Destination Address</b>	HTTPS_Load_Balance
<b>Schedule</b>	always
<b>Service</b>	HTTPS
<b>Action</b>	ACCEPT
<b>Enable NAT</b>	Select this option and select <i>Use Destination Interface Address</i> .

8. Select other security policy options as required.
9. Select *OK*.

## CLI configuration: adding persistence for a specific domain

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`.

For the CLI configuration, both virtual servers include setting `http-cookie-domain` to `.example.org` because HTTP cookie persistence is just required for the `example.org` domain.

First, the configuration for the HTTP virtual IP:

```
config firewall vip
  edit HTTP_Load_Balance
    set type server-load-balance
    set server-type http
    set extport 8080
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
    config realservers
      edit 1
        set ip 10.10.10.1
      next
      edit 2
        set ip 10.10.10.2
      next
      edit 3
        set ip 10.10.10.3
      end
    end
  end
```

Second, the configuration for the HTTPS virtual IP. In this configuration you don't have to set extport to 443 because extport is automatically set to 443 when server-type is set to https.

```
config firewall vip
  edit HTTPS_Load_Balance
    set type server-load-balance
    set server-type https
    set extport 443
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
    config realservers
      edit 1
        set ip 10.10.10.1
      next
      edit 2
        set ip 10.10.10.2
      next
      edit 3
        set ip 10.10.10.3
      end
    end
  end
```

# Chapter 13 Logging and Reporting

This FortiOS Handbook chapter contains the following sections:

[Logging and reporting overview](#) provides general information about logging. We recommend that you begin with this chapter as it contains information for both beginners and advanced users as well. It contains an explanation of log messages, files, and devices, and an overview of the Reporting functions.

[Logging and reporting for small networks](#) provides an overview of setting up a small network for logging, with a look at a possible setup with a backup solution and a customized report.

[Logging and reporting for large networks](#) provides an overview of setting up a larger, enterprise-level network, with configuration of multiple FortiGate units, multiple FortiAnalyzer units as a backup solution, and a sample procedure for creating a more intensive and broad report to suit the larger network.

[Advanced logging](#) provides a series of separate tutorials for possible tasks and procedures an advanced user may want to undertake with their FortiGate-powered network. It contains explanations of advanced backup, logging, and report solutions.

[Troubleshooting and logging](#) provides a short overview of how log messages can be used to identify and solve problems within the network, how to identify and solve logging database issues, and how to solve connection issues between FortiGate and FortiAnalyzer units.

[Appendix: FortiGate report charts](#) provides a detailed list of the variety of charts available for use in FortiGate reporting.

# Logging and reporting overview

Logging and reporting in FortiOS can help you in determining what is happening on your network, as well as informing you of certain network activity, such as detection of a virus or IPsec VPN tunnel errors. Logging and reporting go hand in hand, and can become a valuable tool for information as well as helping to show others the activity that is happening on the network.

This section explains logging and reporting features that are available in FortiOS, and how they can be used to help you manage or troubleshoot issues. This includes how the FortiGate unit records logs, what a log message is, and what the log database is.

The following topics are included in this section:

- [What is logging?](#)
- [Log messages](#)
- [Log files and types](#)
- [Log database and datasets](#)
- [Notifications about network activity](#)
- [Log devices](#)
- [Reports](#)
- [Best Practices: Log management](#)

In FortiOS 5.0, logs have changed and as a result, most log data is preserved and will be updated to the new log format when 5.0 is first installed. However, this log update may take a while, as this includes updating the report charts and datasets. A warning will appear to let you know that this process is still in progress even after the upgrade has finished.

---

## What is logging?

Logging records the traffic passing through the FortiGate unit to your network and what action the FortiGate unit took during its scanning process of the traffic. This recorded information is called a log message.

After a log message is recorded, it is stored within a log file which is then stored on a log device. A log device is a central storage location for log messages. The FortiGate unit supports several log devices, such as the FortiCloud service, or a FortiAnalyzer unit. A FortiGate unit's system memory and local disk can also be configured to store logs, and because of this, are also considered log devices.

You must subscribe to FortiCloud before you will be able to configure the FortiGate unit to send logs to a FortiCloud server.

---

When the recorded activity needs to be read in a more human way, the FortiGate unit can generate a Report. A report gathers all the log information that is needed for the report, and presents it in a graphical format, with customizable design and automatically generated charts. Reports can be used to present a graphical representation of what is going on in the network.

Reports can also be generated on a FortiAnalyzer unit; if you want to generate reports on a FortiAnalyzer, see the [FortiAnalyzer Setup and Administration Guide](#) to help you create and generate those reports.

## How the FortiGate unit records log messages

The FortiGate unit records log messages in a specific order, storing them on a log device. The order of how the FortiGate unit records log messages is as follows:

1. Incoming traffic is scanned.
2. During the scanning process, the FortiGate unit performs necessary actions, and simultaneously records the actions and results.
3. Log messages are sent to the log device.

### Example: How the FortiGate unit records a DLP event

1. The FortiGate unit receives incoming traffic and scans for any matches associated within its firewall policies containing a DLP sensor.
2. A match is found; the DLP sensor, `dlp_sensor`, had a rule within it called All-HTTP with the action Exempt applied to the rule. The sensor also has Enable Logging selected, which indicates to the FortiGate unit that the activity should be recorded and placed in the DLP log file.
3. The FortiGate unit exempts the match, and places the recorded activity (the log message) within the DLP log file.
4. According to the log settings that were configured, logs are stored on the FortiGate unit's local hard drive. The FortiGate unit places the DLP log file on the local hard drive.

## FortiOS features available for logging

Logs record FortiGate activity, providing detailed information about what is happening on your network. This recorded activity is found in log files, which are stored on a log device. However, logging FortiGate activity requires configuring certain settings so that the FortiGate unit can record the activity. These settings are often referred to as log settings, and are found in most Security Features, such as profiles, but also the event log settings.

Log settings provide the information that the FortiGate unit needs so that it knows what activities to record. This topic explains what activity each log file records, as well as additional information about the log file, which will help you determine what FortiGate activity the FortiGate unit should record.

## Traffic

Traffic logs record the traffic that is flowing through your FortiGate unit. Since traffic needs firewall policies to properly flow through the unit, this type of logging is also referred to as firewall policy logging. Firewall policies control all traffic that attempts to pass through the FortiGate unit, between FortiGate interfaces, zones and VLAN sub-interfaces.

Logging traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic or Log Violation Traffic)
- packet comes into an inbound interface
- a possible log packet is sent regarding a match in the firewall policy, such as URL filter
- traffic log packet is sent, per firewall policy
- packet passes and is sent out an interface

Traffic log messages are stored in the traffic log file. Traffic logs can be stored any log device, even system memory.

All Security Feature-related logs are now tracked within the Traffic logs, as of FortiOS 5.0, so all forward traffic can be searched in one place, such as if you are looking to see all activity from a particular address, security feature or traffic.

The *Security Feature Log* section has been removed from the default interface, but if your device is registered with FortiCloud, *Security Log* may still appear in the web interface, and will list the security feature traffic separately, as FortiCloud tracks it separately from traffic. If you would like to be able to view the security feature logs both within and isolated from the Traffic logs, registering with FortiCloud is necessary.

If you have enabled and configured WAN Optimization, you can enable logging of this activity in the CLI using the `config wanopt setting` command. These logs contain information about WAN Optimization activity and are found in the traffic log file. When configuring logging of this activity, you must also enable logging within the security policy itself, so that the activity is properly recorded.

## Other Traffic

The traffic log also records interface traffic logging, which is referred to as other traffic. Other traffic is enabled only in the CLI. When enabled, the FortiGate unit records traffic activity on interfaces as well as firewall policies. Logging other traffic puts a significant system load on the FortiGate unit and should be used only when necessary.

Logging other traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic or Log Violation Traffic) and other-traffic
- packet comes into an interface
- interface log packet is sent to the traffic log that is enabled on that particular interface
- possible log packet is sent regarding a match in the firewall policy, such as URL filter
- interface log packet is sent to the traffic log if enabled on that particular interface
- packet passes and is sent out an interface
- interface log packet is sent to traffic (if enabled) on that particular interface

## Event

The event log records administration management as well as FortiGate system activity, such as when a configuration has changed, admin login, or high availability (HA) events occur. Event logs are an important log file to record because they record FortiGate system activity, which provides valuable information about how your FortiGate unit is performing.

Event logs help you in the following ways:

- keeping track of configuration setting changes
- IPsec negotiation, SSL VPN and tunnel activity
- quarantine events, such as banned users
- system performance
- HA events and alerts
- firewall authentication events
- wireless events on models with WiFi capabilities
- activities concerning modem and internet protocols L2TP, PPP and PPPoE
- VIP activities
- AMC disk's bypass mode
- VoIP activities that include SIP and SCCP protocols.

The FortiGate unit records event logs only when events are enabled.

## Traffic Shaping

Traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings can be applied to a firewall policy, appearing within the traffic log messages.

By enabling this feature, you can see what traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings are being used.

## Data Leak Prevention

Data Leak Prevention logs, or DLP logs, provide valuable information about the sensitive data trying to get through to your network as well as any unwanted data trying to get into your network. The DLP rules within a DLP sensor can log the following traffic types:

- email (SMTP, POP3 or IMAP; if SSL content SMTPS, POP3S, and IMAPS)
- HTTP
- HTTPS
- FTP
- NNTP
- IM

A DLP sensor must have log settings enabled for each DLP rule and compound rule, as well as applied to a firewall policy so that the FortiGate unit records this type of activity. A DLP sensor can also contain archiving options, which these logs are then archived to the log device.

## NAC Quarantine

Within the DLP sensor, there is an option for enabling NAC Quarantine. The NAC Quarantine option allows the FortiGate unit to record details of DLP operation that involve the ban and quarantine actions, and sends these to the event log file. The NAC Quarantine option must also be enabled within the Event Log settings. When enabling NAC quarantine within a DLP Sensor, you must enable this in the CLI because it is a CLI-only command.

## Media Access Control (MAC) Address

MAC address logs provide information about MAC addresses that the FortiGate unit sees on the network as well as those removed from the network. These log messages are stored in the

event log (as subtype network; you can view these log messages in Log & Report > Event > Event Log) and are, by default, disabled in the CLI. You can enable logging MAC addresses using the following command syntax:

```
config log setting
    set neighbor-event enable
end
```

When enabled, a new log message is recorded every time a MAC address entry is added to the ARP table, and also when a MAC address is removed as well. A MAC address log message is also recorded when MAC addresses are connected to the local switch, or from a FortiAP or FortiSwitch unit.

## Application control

Application control logs provide detailed information about the traffic that internet applications such as Skype are generating. The application control feature controls the flow of traffic from a specific application, and the FortiGate unit examines this traffic for signatures that the application generates.

The log messages that are recorded provide information such as the type of application being used (such as P2P software), and what type of action the FortiGate unit took. These log messages can also help you to determine the top ten applications that are being used on your network. This feature is called application control monitoring and you can view the information from a widget on the Executive Summary page.

The application control list that is used must have *Enabled Logging* selected within the list, as well as logging enabled within each application entry. Each application entry can also have packet logging enabled. Packet logging for application control records the packet when an application type is identified, similar to IPS packet logging.

Logging of application control activity can only be recorded when an application control list is applied to a firewall policy, regardless of whether or not logging is enabled within the application control list.

## Antivirus

Antivirus logs are recorded when, during the antivirus scanning process, the FortiGate unit finds a match within the antivirus profile, which includes the presence of a virus or grayware signature. Antivirus logs provide a way to understand what viruses are trying to get in, as well as additional information about the virus itself, without having to go to the FortiGuard Center and do a search for the detected virus. The link is provided within the log message itself.

These logs provide valuable information such as:

- the name of the detected virus
- the name of the oversized file or infected file
- the action the FortiGate unit took, for example, a file was blocked
- URL link to the FortiGuard Center which gives detailed information about the virus itself

The antivirus profile must have log settings enabled within it so that the FortiGate unit can record this activity, as well as having the antivirus profile applied to a firewall policy.

## Web Filter

Web filter logs record HTTP traffic activity. These log messages provide valuable and detailed information about this particular traffic activity on your network. Web filtering activity is important to log because it can inform you about:

- what types of web sites employees are accessing
- users attempting to access banned web sites and how often this occurs
- network congestion due to employees accessing the Internet at the same time
- web-based threats resulting from users visiting non-business-related web sites

Web Filter logs are an effective tool to help you determine if you need to update your web filtering settings within a web filter profile due to unforeseen threats or network congestion. These logs also inform you about web filtering quotas that have been configured for filtering HTTP traffic.

You must configure logging settings within the web filter profile and apply the filter to a firewall policy so that the FortiGate unit can record the activity.

## IPS (attack)

IPS logs, also referred to as attack logs, record attacks that occurred against your network. Attack logs contain detailed information about whether the FortiGate unit protected the network using anomaly-based defense settings or signature-based defense settings, as well as what the attack was.

The IPS or attack log file is especially useful because the log messages that are recorded contain a link to the FortiGuard Center, where you can find more information about the attack. This is similar to antivirus logs, where a link to the FortiGuard Center is provided as well that informs you of the virus that was detected by the FortiGate unit.

An IPS sensor with log settings enabled must be applied to a firewall policy so that the FortiGate unit can record the activity.

## Packet logs

When you enable packet logging within an IPS signature override or filter, the FortiGate unit examines network packets, and if a match is found, saves them to the attack log. Packet logging is designed to be used as a diagnostic tool that can focus on a narrow scope of diagnostics, rather than a log that informs you of what is occurring on your network.

You should use caution when enabling packet logging, especially within IPS filters. Filter configuration that contains thousands of signatures could potentially cause a flood of saved packets, which would take up a lot of storage space on the log device. It would also take a great deal of time to sort through all the log messages, as well as consume considerable system resources to process.

You can archive packets, but you must enable this option on the Log Settings page. If your log configuration includes multiple FortiAnalyzer units, packet logs are only sent to the primary (first) FortiAnalyzer unit. Sending packet logs to the other FortiAnalyzer units is not supported.

## Email filter

Email filter logs, also referred to as spam filter logs, records information regarding the content within email messages. For example, within an email filter profile, a match is found that finds the email message to be considered spam.

Email filter logs are recorded when the FortiGate unit finds a match within the email filter profile and logging settings are enabled within the profile.

## Archives (DLP)

Recording DLP logs for network use is called DLP archiving. The DLP engine examines email, FTP, IM, NNTP, and web traffic. Archived logs are usually saved for historical use and can be accessed at any time. IPS packet logs can also be archived, within the Log Settings page.

You can start with the two default DLP sensors that have been configured specifically for archiving log data, Content\_Archive and Content\_Summary. They are available in *Security Profiles > Data Leak Prevention > Sensors*. Content\_Archive provides full content archiving, while Content\_Summary provides summary archiving. For more information about how to configure DLP sensors, see the Security Features chapter of the FortiOS Handbook.

You must enable the archiving to record log archives. Logs are not archived unless enabled, regardless of whether or not the DLP sensor for archiving is applied to the firewall policy.

## Network scan

Network scan logs are recorded when a scheduled scan of the network occurs. These log messages provide detailed information about the network's vulnerabilities regarding software, as well as the discovery of any further vulnerabilities.

A scheduled scan must be configured and logging enabled within the Event Log settings, for the FortiGate unit to record these log messages.

## Log messages

Log messages are recorded by the FortiGate unit, giving you detailed information about the network activity. Each log message has a unique number that helps identify it, as well as containing fields; these fields, often called log fields, organize the information so that it can be easily extracted for reports.

These log fields are organized in such a way that they form two groups: the first group, made up of the log fields that come first, is called the log header. The log header contains general information, such as the unique log identification and date and time that indicates when the activity was recorded. The log body is the second group, and contains all the other information about the activity. There are no two log message bodies that are alike, however, there may be fields common to most log bodies, such as the `srcintf` or `identidix` log fields.

The log header also contains information about the log priority level which is indicated in the `level` field. The priority level indicates the immediacy and the possible repercussions of the logged action. For example, if the field contains 'alert', you need to take immediate action with regards to what occurred. There are six log priority levels.

The log severity level is the level at and above which the FortiGate unit records logs. The log severity level is defined by you when configuring the logging location. The FortiGate unit will log all messages at and above the priority level you select. For example, if you select Error, the unit will log only Error, Critical, Alert, and Emergency level messages.

**Table 78:** Log priority levels

Levels	Description
0 - Emergency	The system has become unstable.
1 - Alert	Immediate action is required.
2 - Critical	Functionality is affected.

**Table 78:** Log priority levels

Levels	Description
3 - Error	An error condition exists and functionality could be affected.
4 - Warning	Functionality could be affected.
5 - Notification	Information about normal events.
6 - Information	General information about system operations.

The Debug priority level, not shown in [Table 78](#), is rarely used. It is the lowest log priority level and usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly.

**Table 79:** Example log header fields

Log header	
date=(2010-08-03)	The year, month and day of when the event occurred in yyyy-mm-dd format.
time=(12:55:06)	The hour, minute and second of when the event occurred in the format hh:mm:ss.
log_id=(2457752353)	A five or ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message.
type=(dlp)	The section of system where the event occurred.
subtype=(dlp)	The subtype category of the log message. See <a href="#">Table 78 on page 1936</a> .
level=(notice)	The priority level of the event. See <a href="#">Table 78 on page 1936</a> .
vd=(root)	The name of the virtual domain where the action/event occurred in. If no virtual domains exist, this field always contains root.

**Table 80:** Example log body fields

Log body	
policyid=(1)	The ID number of the firewall policy that applies to the session or packet. Any policy that is automatically added by the FortiGate will have an index number of zero.
identidx=(0)	The identity-based policy identification number. This field displays zero if the firewall policy does not use an identity-based policy; otherwise, it displays the number of the identity-based policy entry that the traffic matched. This number is not globally unique, it is only locally unique within a given firewall policy.
sessionid=(311)	The serial number of the firewall session of which the event happened.

**Table 80:** Example log body fields

Log body	
srcip=(10.10.10.1)	The source IP address.
srcport=(1190)	The source port number.
srcintf=(internal)	The source interface name.
dstip=(192.168.1.122)	The destination IP address.
dstport=(80)	The destination port number.
dstintf=(wan1)	The destination interface name.
service=(https)	The IP network service that applies to the session or packet. The services displayed correspond to the services configured in the firewall policy.
status=(detected)	The action the FortiGate unit took.
hostname=(example.com)	The home page of the web site.
url=(/image/trees_pine_forest/)	The URL address of the web page that the user was viewing.
msg=(data leak detected(Data Leak Prevention Rule matched)	Explains the FortiGate activity that was recorded. In this example, the data leak that was detected matched the rule, All-HTTP, in the DLP sensor.
rulename=(All-HTTP)	The name of the DLP rule within the DLP sensor.
action=(log-only)	The action that was specified within the rule. In some rules within sensors, you can specify content archiving. If no action type is specified, this field display log-only.
severity=(1)	The level of severity for that specific rule.

Logs from other devices, such as the FortiAnalyzer unit and Syslog server, contain a slightly different log header. For example, when viewing FortiGate log messages on the FortiAnalyzer unit, the log header contains the following log fields when viewed in the Raw format:

```
itime=1302788921 date=20110401 time=09:04:23 devname=FG50BH3G09601792
device_id=FG50BH3G09601792 log_id=0100022901 type=event
subtype=system level=notice vd=root
```

The log body contains the rest of the information of the log message, and this information is unique to the log message itself.

For detailed information on all log messages, see the [FortiGate Log Message Reference](#). For more information about how to understand a log message, see the [FortiGate Cookbook](#).

## Explanation of a debug log message

Debug log messages are only generated if the log severity level is set to Debug. The Debug severity level is the lowest log severity level and is rarely used. This severity level usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly. Debug log messages are generated by all types of FortiGate features.

The following is an example of a debug log message:

```
date=2010-01-25 time=17:25:54 logid=93000000000 type=utm
  subtype=webfilter eventtype=urlfilter level=debug msg="found in
  cache"
```

**Table 81:** Example of a Debug log message

Debug log	
date=(2010-01-25)	The year, month and day of when the event occurred in the format yyyy-mm-dd.
time=(17:25:54)	The hour, minute and second of when the event occurred in the format hh:mm:ss.
logid=(93000000000)	A ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message.
type=(utm)	The section of system where the event occurred.
subtype=(webfilter)	The subtype of the log message, the UTM profile in a UTM log message.
eventtype=(urlfilter)	The event type of the log message. This represents a policy applied to the FortiGate feature in the firewall policy.
level=(debug)	The priority level of the event. There are six priority levels to specify.
msg=("found in cache")	Explains the activity or event that the FortiGate unit recorded.
msg=("found in cache")	Explains the activity or event that the FortiGate unit recorded.

## Viewing log messages and archives

Depending on the log device, you may be able to view logs within the web-based manager or CLI on the FortiGate unit. If you have configured a FortiAnalyzer unit, local hard disk, or system memory, you can view log messages from within the web-based manager or CLI. If you have configured either a Syslog or WebTrends server, you will not be able to view log messages from the web-based manager or CLI. There is also no support for viewing log messages stored on a FortiCloud server, from the FortiGate unit's web-based manager or CLI.

You do not have to view log messages from only the web-based manager. You can view log messages from the CLI as well, using the `execute log display` command. This command allows you to see specific log messages that you already configured within the `execute log filter` command. The `execute log filter` command configures what log messages you will see, how many log messages you can view at one time (a maximum of 1000 lines of log messages), and the type of log messages you can view. For more information about viewing log messages in the CLI, see ["Viewing logs from the CLI" on page 1971](#).

There are two log viewing options in FortiOS: Format and Raw. The Raw format displays logs as they appear within the log file. You can view log messages in the Raw format using the CLI or a text editor, such as Notepad. Format is in a more human-readable format, and you can easily filter information when viewing log messages this way. The Format view is what you see when viewing logs in the web-based manager.

When you download the log messages from within the log message page (for example, *Log & Report > Traffic Log > Forward Traffic*), you are downloading log messages in the Raw format.

## Viewing log messages in detail

From any log page, you can view detailed information about the log message in the log viewer table, located (by default) at the bottom of the page. Each page contains this log viewer table. The Log Viewer Table can contain the Archive tab, which allows you to see the archived version of the log message. The Archive tab only displays the archived log's details if archiving is enabled and logs are being archived by the FortiGate unit, but archived logs will also be recorded when using a FortiAnalyzer unit or the FortiCloud service.

When you are viewing traffic log messages, some of the categories (such as 'Application Name') have entries that can be selected to open a dialog box containing FortiGuard information about the entry. From within the dialog box, you can select the Reference link and go directly to the corresponding FortiGuard page, which contains additional information.

Viewing logs in Raw format allows you to view all log fields at once, as well as have a log file available regardless of whether you are archiving logs or not. You download the log file by selecting *Download Raw Log*. The log file is named in the following format: `<log_type><log_location><log_date/time>.<log_number>.log`. For example, `SystemEventLog-disk-2012-09-19T12_13_46.933949.log`, which is an event log. The time period is the day and month of when the log was downloaded, not the time period of the log messages within the file itself.

## Quarantine

Within the Log & Report menu, you can view detailed information about each quarantined file. The information can either be sorted or filtered, depending on what you want to view.

You must enable quarantine settings within an antivirus profile and the destination must be configured in the CLI using the `config antivirus quarantine` command. The destination can be either a FortiAnalyzer unit or local disk.

Sort the files by file name, date, service, status, duplicate count (DC), or time to live (TTL). Filter the list to view only quarantined files with a specific status or from a specific service.

On *Log & Report > Quarantine*, the file quarantine list displays the following information about each quarantined file.

### Quarantine page

Lists all files that are considered quarantined by the unit. On this page you can filter information so that only specific files are displayed on the page.

GUI Item	Description
<b>Source</b>	Either <i>FortiAnalyzer</i> or <i>Local disk</i> , depending where you configure to quarantined files to be stored.
<b>Sort by</b>	Sort the list. Choose from: <i>Status</i> , <i>Service</i> , <i>File Name</i> , <i>Date</i> , <i>TTL</i> , or <i>Duplicate Count</i> . Select <i>Apply</i> to complete the sort.

<b>Filter</b>	<p>Filter the list. Choose either <i>Status</i> (infected, blocked, or heuristics) or <i>Service</i> (IMAP, POP3, SMTP, FTP, HTTP, MM1, MM3, MM4, MM7, IM, or NNTP). Select <i>Apply</i> to complete the filtering. Heuristics mode is configurable through the CLI only.</p> <p>If your unit supports SSL content scanning and inspection Service can also be IMAPS, POP3S, SMTPS, or HTTPS. For more information, see the Security Features chapter of the FortiOS Handbook.</p>
<b>Apply</b>	Select to apply the sorting and filtering selections to the list of quarantined files.
<b>Delete</b>	Select to delete the selected files.
<b>Page Controls</b>	Use the controls to page through the list.
<b>Remove All Entries</b>	<p>Removes all quarantined files from the local hard disk.</p> <p>This icon only appears when the files are quarantined to the hard disk.</p>
<b>File Name</b>	<p>The file name of the quarantined file. When a file is quarantined, all spaces are removed from the file name, and a 32-bit checksum is performed on the file. The checksum appears in the replacement message but not in the quarantined file. The file is stored on the Fortinet hard disk with the following naming convention:</p> <p>&lt;32bit_CRC&gt;.&lt;processed_filename&gt;</p> <p>For example, a file named Over Size.exe is stored as 3fc155d2.oversize.exe.</p>
<b>Date</b>	The date and time the file was quarantined, in the format dd/mm/yyyy hh:mm. This value indicates the time that the first file was quarantined if duplicates are quarantined.
<b>Service</b>	The service from which the file was quarantined (HTTP, FTP, IMAP, POP3, SMTP, MM1, MM3, MM4, MM7, IM, NNTP, IMAPS, POP3S, SMTPS, or HTTPS).
<b>Status</b>	The reason the file was quarantined: <i>infected</i> , <i>heuristics</i> , or <i>blocked</i> .
<b>Status Description</b>	Specific information related to the status, for example, "File is infected with "W32/Klez.h"" or "File was stopped by file block pattern."
<b>DC</b>	Duplicate count. A count of how many duplicates of the same file were quarantined. A rapidly increasing number can indicate a virus outbreak.
<b>TTL</b>	<p>Time to live in the format hh:mm. When the TTL elapses, the Fortinet unit labels the file as EXP under the TTL heading. In the case of duplicate files, each duplicate found refreshes the TTL.</p> <p>The TTL information is not available if the files are quarantined on a FortiAnalyzer unit.</p>
<b>Upload status</b>	<p>Y indicates the file has been uploaded to Fortinet for analysis, N indicates the file has not been uploaded.</p> <p>This option is available only if the Fortinet unit has a local hard disk.</p>

- Download** Select to download the corresponding file in its original format.  
This option is available only if the Fortinet unit has a local hard disk.
- Submit** Select to upload a suspicious file to Fortinet for analysis.  
This option is available only if the Fortinet unit has a local hard disk.

### Customizing the display of log messages on the web-based manager

Customizing log messages on the web-based manager allows you to remove or add columns from the page and filter the information that appears. For example, you can view only log messages that appeared on December 4, between the hours of 8:00 and 8:30 am.

1. Select the submenu in **Log & Report** in which you want to customize the display of log messages, such as *Log & Report > Traffic Log > Forward Traffic*.
2. Right click on the title bar at the top of any column, and select *Column Settings*. This will change what columns will display on the page.
3. In the section at the top, uncheck a column title such as **Date/Time** to remove it from the interface. Check other columns to add them to the interface. When you are finished, click outside the menu and the page will refresh with the new column settings in place.
4. Choose a column you'd like to filter, and select the funnel icon next to the title of the column. For example, select the funnel in the Src (Source) column. In the text field, enter the source IP address 1.1.1.1 and then select the check box beside **NOT**.

This filters out the all log messages that have the 1.1.1.1 source IP address in the source IP log field, such as the ones generated when running log tests in the CLI.

5. Select **OK** to save the customize settings, and then view the log messages on the page.  
Log messages that originate from the 1.1.1.1 source address will no longer appear in the list.

### How to download log messages and view them from on a computer

After recording some activity, you can download log messages to view them from a computer. This is can be very useful when in a remote location, or if you want to view log messages at your convenience, or to view packet logs or traffic logs.

1. In Log & Report, select the submenu that you want to download log messages from.  
For example, *Log & Report > Traffic Log> Forward Traffic*.
2. Select the **Download Raw Log** option and save the log file to your computer.  
The log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.
3. Open a text editor such as Notepad, open the log file, and then scroll to view all the log messages.

You can easily search or scroll through the logs to see the information that is available.

## Log files and types

As the log messages are being recorded, log messages are also being put into different log files. The log file contains the log messages that belong to that log type, for example, traffic log messages are put in the traffic log file.

When downloading the log file from within *Log & Report*, the file name indicates the log type and the device on which it is stored, as well as the date, time, and a unique id for that log.

This name is in the format <logtype> - <logdevice> - <date> T <time> . <id>.log.

For example, AntiVirusLog-disk-2012-09-13T11\_07\_57.922495.log.

Below, each of the different log files are explained. Traffic and Event logs come in multiple types, but all contain the base type such as 'Event' in the filename.

**Table 82: Log Types based on network traffic**

Log Type	Description
Traffic	The traffic logs records all traffic to and through the FortiGate interface. Different categories monitor different kinds of traffic, whether it be external, internal, or multicast.
Event	The event logs record management and activity events within the device in particular areas: System, Router, VPN, User, WAN, and WiFi. For example, when an administrator logs in or logs out of the web-based manager, it is logged both in System and in User events.
Antivirus	The antivirus log records virus incidents in Web, FTP, and email traffic.
Web Filter	The web filter log records HTTP FortiGate log rating errors including web content blocking actions that the FortiGate unit performs.
Intrusion	The intrusion log records attacks that are detected and prevented by the FortiGate unit.
Email Filter	The email filter log records blocking of email address patterns and content in SMTP, IMAP, and POP3 traffic.
Vulnerability Scan	The Vulnerability Scan (Netscan) log records vulnerabilities found during the scanning of the network.
Data Leak Prevention	The Data Leak Prevention log records log data that is considered sensitive and that should not be made public. This log also records data that a company does not want entering their network.
VoIP	The VoIP log records VoIP traffic and messages. It only appears if VoIP is enabled on the Administrator Settings page.

## Log database and datasets

The log database, also known as the SQL log database, is used to store logs on the FortiGate unit itself. The log database uses Structured Query Language (SQL), specifically it uses SQLite which is an embedded Relational Database Management System (RDBMS).

If you have disabled SQL logging and have factory defaults on the FortiGate unit, and then you upgrade the firmware, the upgrade will automatically disable SQL logging. When this occurs, you must re-enable SQL logging manually.

The FortiGate unit creates a database table for each log type, when log data is recorded. If the FortiGate unit is not recording log data, it does not create log tables for that device.

The command syntax, `get report database schema`, allows you to view all the tables, column names and types that are available to use when creating SQL statements for datasets.

If you want to view the size of the database, as well as the log database table entries, use the `get report sql status` command. This command displays the amount of free space that is available as well as the first and last log database entry time and date.

The output of the `get log sql status` command contains information similar to the following:

```
Database size: 294912
Free size in database: 0
Database Page Size: 8192
Entry number:
    Event: 49
    Traffic: 370
    Attack: 2
    AntiVirus: 4
    WebFilter: 254
    AntiSpam: 2
    Netscan: 18
    Total: 699
First entry time: 2012-09-10 11:41:02
Last entry time: 2012-09-13 02:59:59
```

The log database is not only used to store logs, but also used to extract the information for reports. Reports are built from datasets, which are SQL statements that tell the FortiGate unit how to extract the information from the database. You can create your own datasets; however, SQL knowledge is required. Default datasets are available for reports.

## How to view datasets

If you want to view the list of all default datasets, use the following command syntax in the CLI (the question mark on the end is to display the list of existing entries):

```
diagnose report dataset ?
```

If you want to view the format of a created dataset, use the following command syntax in the CLI:

```
config report dataset
    show report dataset <dataset_name>
```

## How to create datasets (advanced)

Creating a dataset requires SQL language knowledge. The following is a short high-level summary of how to create a dataset. It assumes that you have SQL language knowledge, and therefore is for advanced users only.

1. Log in to the CLI and use the `config report dataset` command to start creating the dataset.

You can name the dataset any name; however, it should be a name that describes what information is contained in the dataset. For example, `wanopt.traffic.bandwidth.24h` dataset name indicates that the dataset contains only WAN Optimization traffic and the amount of bandwidth that has been used for the past 24 hours.

2. Set the various variables within the dataset as you need for your report. Refer to the [FortiGate CLI Reference](#) to see the complete list of commands and variables you will need.

The following table shows a possible method for customizing a dataset to output a list of the top ten bandwidth consuming applications within an hour.

<pre>config report dataset</pre>	
<pre>edit appctrl.Count.Bandwidth.Top10.Apps</pre>	
<pre>set query "select (timestamp-timestamp%3600) as hourstamp"</pre>	This calculates an "hourstamp" to indicate the bandwidth per hour.
<pre>(Case WHEN app!=\'N/A\' and app!=\'\' then app ELSE service END) as appname</pre>	Uses the application name, appname, or if it is undefined, uses service instead.
<pre>as bandwidth from traffic_log where ###timestamp_to_oid(traffic_log)###</pre>	This states to retrieve the information from the traffic log file.
<pre>and (appname in (select (CASE WHEN app!=\' N/A\' and app!=\'\' then app ELSE service END) as appname from traffic_log where ###timestamp_to_oid(traffic_log)### group by appname order by sum(sent+rcvd) desc limit 10)) group by hourstamp, appname order by hourstamp desc"</pre>	From this information, the FortiGate unit selects the application name from within the specific traffic log message and groups these names in order by the top ten, as well as by the "hourstamp" in descending order.

3. Create a corresponding chart using the `config report chart` command, making sure to apply the dataset that you just configured to the chart.

The custom dataset is now available for use in a report.

If you want to modify an existing dataset that you've created, the process is the same. Enter `config report dataset` in the CLI followed by the name of the existing dataset.

To see the list of created datasets, enter the following in the CLI:

```
config report dataset
show
```

## Notifications about network activity

Alert email messages provide notification about activities or events logged. These email messages also provide notification about log severities that are recorded, such as a critical or emergency.

You can send alert email messages to up to three email addresses. Alert messages are also logged and can be viewed from the Event Log menu, in the System Event log file.

You can use the alert email feature to monitor logs for log messages, and to send email notification about a specific activity or event logged. For example, if you require notification about administrators logging in and out, you can configure an alert email that is sent whenever an administrator logs in and out. You can also base alert email messages on the severity levels of the logs. The FortiGate unit does not currently support SSL/TLS connections for SMTP servers, so you must choose an SMTP server that does not need SSL/TLS when configuring the SMTP server settings.

Before configuring alert email, you must configure at least one DNS server if you are configuring with an Fully Qualified Domain Server (FQDN). The FortiGate unit uses the SMTP server name to

connect to the mail server, and must look up this name on your DNS server. You can also specify an IP address.

The default minimum log severity level is Alert. If the FortiGate unit collects more than one log message before an interval is reached, the FortiGate unit combines the messages and sends out one alert email.

## How to configure email notifications

The following explains how to configure an alert email notification for IPsec tunnel errors, firewall authentication failure, configuration changes and FortiGuard license expiry.

1. In **System > Config > Messaging Services**, configure the SMTP server.

The SMTP server settings allow the FortiGate unit to know exactly where the email will be sent from, as well as who to send it to. The SMTP server must be a server that does not support SSL/TLS connections; if the SMTP server does, the alert email configuration will not work. The FortiGate unit does not currently support SSL/TLS connections for SMTP servers.

2. In **Log & Report > Log Config > Alert E-mail**, enter the source email in the Email From field, and up to three target addresses in the Email To fields.
3. Below the email entry, you can configure the email responses. By default, the **Send alert email for the following** is enabled. Select the check boxes beside **IPsec tunnel errors**, **Configuration changes** and **Firewall authentication failure**.

These alerts will be sent to the email address specified when the trigger occurs. For example, a user attempts to connect to the branch office of the company but cannot; the FortiGate unit detects an IPsec tunnel error, records the event, and then sends the notice to the email address specified in the SMTP server settings.

4. Select **FortiGuard license expiry time**: and then enter 10 so that the email notification will be sent ten days prior to the FortiGuard license expiration.

You can choose up to 100 days prior to when the license will expire. The default time is 15 days. By using this alert email notification, you can easily know when to send an re-registration request long before the expiry.

## Log devices

The FortiGate unit supports a variety of log devices, including the FortiCloud service and FortiAnalyzer units. This provides greater flexibility not only when choosing a log device, but also when your logging requirements need updating.

When you have developed a plan that meets your logging needs and requirements, you need to select the log device that is appropriate for that plan. A log device must be able to store all the logs you need, and if you require archiving those logs, you must consider what log devices support this option.

During this process of deciding what log device meets your needs and requirements, you must also figure out how to provide a backup solution in the event the log device that the FortiGate unit is sending logs to has become unavailable. A backup solution should be an important part of your log setup because it helps you to maintain all logs and prevents lost logs, or logs that are not sent to the log device. For example, a daily backup of log files to the FortiAnalyzer unit occurs at 5 pm.

Log devices provide a central location for storing logs recorded by the FortiGate unit. The following are log devices that the FortiGate unit supports:

- FortiGate system memory
- Hard disk or AMC
- SQL database (for FortiGate units that have a hard disk)
- FortiAnalyzer unit
- FortiCloud service
- Syslog server
- NetIQ WebTrends server

These log devices, except for the FortiGate system memory and local hard disk, can also be used as a backup solution. For example, you can configure logging to the FortiGate unit's local disk, but also configure logging to a FortiCloud server and archive logs to both the FortiCloud server and a FortiAnalyzer unit, and disk logging does not need to be enabled for these alternate log solutions to continue logging.

If you are formatting a disk that contains more than just logs, all information on the disk will be lost.

---

## FortiGate unit's system memory and hard disk

The FortiGate unit's system memory and hard disk can store all log types, including log archives and traffic logs. Traffic logs and log archives are larger files, and need a lot of room when being logged by the FortiGate unit.

When the system memory is full, the FortiGate unit overwrites the oldest messages, and all log messages stored in memory are cleared when the FortiGate unit restarts. By default, logging to memory is enabled. This means that most of the time you will only need to modify the default settings to your network logging requirements. Real-time logging occurs whenever memory logging is enabled, and is enabled by default. Real-time logging means that the activity is being recorded as it happens.

All FortiGate units 100D and larger are capable of disk logging, but it is disabled by default, as it is not recommended. For flash memory-based units, constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. For hard-disk units, it can affect performance under heavy strain. Therefore, disk logging must be manually enabled in the CLI under `config log disk setting` to appear in the interface at all.

Models without a hard disk are not recommended for disk logging. For all units, disk logging must be enabled in the CLI. For some low-end and older models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

---

When logging to the FortiGate unit's hard disk or memory, you can configure logging to a FortiAnalyzer unit, which will log independently of the hard disk.

If you are registered with the FortiCloud service, your unit will log both locally and to the service by default. In order to configure the rate and time of uploads to the service, you must register a contract account for the FortiCloud service, which will also grant you additional space.

## FortiAnalyzer unit

The FortiAnalyzer unit can log all FortiGate features, which includes log archives. You can also configure the FortiGate unit to upload logs to the FortiAnalyzer unit at a scheduled time.

Encryption of the logs is supported by default and logs are sent using IPsec or SSL VPN. When the FortiAnalyzer and FortiGate units have SSL encryption, both must choose a setting for the enc-algorithm command (CLI) for encryption to take place. By default, this is enabled and the default setting is a SSL communication with high and medium encryption algorithms. The setting that you choose must be the same for both.

FortiGate units can support logging to multiple FortiAnalyzer units. This logging solution is a backup redundancy solution, since logs are sent to all three units and whenever one of the FortiAnalyzer units fails, the others still carry on storing logs.

If you are using evaluation software FortiGate and FortiAnalyzer-VM images, you will only be able to use low-level encryption.

The FortiGate unit can also connect to a FortiAnalyzer unit using Automatic Discovery. Automatic Discovery is a method of establishing a connection to a FortiAnalyzer unit by using the FortiGate unit to find a FortiAnalyzer unit on the network. The Fortinet Discovery Protocol (FDP) is used to locate the FortiAnalyzer unit. Both the FortiGate and FortiAnalyzer units must be on the same subnet to use FDP, and they must also be able to connect using UDP.

When you enable automatic discovery in the CLI, the FortiGate unit uses HELLO packets to locate any FortiAnalyzer units that are available on the network within the same subnet. When the FortiGate unit discovers a FortiAnalyzer unit, the FortiGate unit automatically enables logging to the FortiAnalyzer unit and begins sending log data.

## Syslog server

The Syslog server is a remote computer running syslog software. Syslog is a standard for forwarding log messages in an IP network, and can be used when considering a log backup solution for your network logging requirements.

FortiGate units support the reliable syslog feature, which is based on RFC 3195. Reliable syslog logging uses TCP, which ensures that connections are set up, including that packets are transmitted.

There are several profiles available for reliable syslog, but only the RAW profile is currently supported on the FortiGate units. The RAW profile is designed to provide a high-performance, low-impact footprint using essentially the same format as the existing UDP-based syslog service.

When enabling the reliable syslog (available only in the CLI), TCP is used. The feature is disabled by default, and when enabled, the FortiGate unit automatically changes the port number to TCP 601. This is based on RFC 3195. The default port for syslog is port 514.

## WebTrends server

A WebTrends server is a remote computer, similar to a Syslog server, running NetIQ WebTrends firewall reporting server. FortiGate log formats comply with WebTrends Enhanced Log Format (WELF) and are compatible with NetIQ WebTrends Security Reporting Center and Firewall Suite 4.1.

You can configure a WebTrends server only in the CLI.

## How to choose a log device for your network topology

When planning the log requirements, you must also consider your network's topology and whether archiving is required, such as if there is a legal requirement to keep a historical record of network activity. The following explains what steps to take when choosing a log device for your specific network topology.

1. What is the scope of your network topology?

If it is a SOHO/SMB network, then logging to the FortiGate unit's local hard disk or the default FortiCloud service would be efficient. If the network topology is a large enterprise, you will need FortiAnalyzer units, a FortiCloud contract, Syslog servers, or any combination.

2. Is archiving required?

If the network activity that is being logged needs to be archived, then, depending on your network topology, you would choose a FortiAnalyzer unit. FortiAnalyzer units store archives in the same way that FortiGate units do, but are able to store large amounts of logs and archives.

3. When troubleshooting issues, you may want to log features such as traffic, that would not be logged otherwise; how much storage space will you need?

Logs can be configured to roll, which is similar to zipping a file; this will lower the space requirements needed to contain them. You can also download logs from the FortiGate unit and save them on a server or on a computer to view and access later, to prevent them from piling up and being overwritten. If you're only temporarily logging a larger amount of traffic, you could upload the logs to an FTP server or cloud service to ensure that these logs are not lost even after you are finished correcting the issue.

4. Should I invest in a log device that can grow as my network grows?

All networks grow, so investing in a device that can grow with your network and that can be expanded is a good investment. For example, if you currently have a SOHO/SMB topology, but see growth already starting, a FortiAnalyzer unit would be best. A FortiAnalyzer unit provides ample storage space, as well as you can add two more FortiAnalyzer units to access additional storage and create a redundancy log backup solution.

## How to create a backup solution for logging

The following helps to explain how to create a log backup solution for a small network topology. This example has one FortiAnalyzer unit and a subscription to the FortiCloud Service.

**Figure 294:**Example of an integrated FortiAnalyzer unit and Syslog servers in a network

1. Log in to the CLI and modify what features will be logged to the FortiAnalyzer unit as well as the settings to the default log device, the FortiGate unit's hard drive.  
By default, the FortiGate unit logs to either the system memory or hard drive, whichever is available on the FortiGate unit. Low-end FortiGate units usually have the system memory enabled for logging by default.
2. In the CLI, use the `config log fortianalyzer setting` command to configure logging to the FortiAnalyzer unit.  
You can only configure log settings for the FortiAnalyzer unit in the CLI. Configuring to upload logs to a FortiAnalyzer unit can be configured in both the CLI and web-based manager.
3. In the CLI, configure the settings for the Syslog server; also enable reliable syslog as well.  
Reliable syslog ensures that logs are sent to the syslog server. When you enable this setting, the default port becomes port 601.

## Reports

Reports provide a way to analyze log data without manually going through a large amount of logs to get to the information you need. This section explains how to configure a FortiOS report and how to modify the existing default FortiOS Security Features report. The FortiOS default Security Features report is a report that gathers security feature activity information and compiles it into a report. This section also explains how to view these reports.

Reports provide a clear, concise overview of what is happening on your network based on log data, without manually going through large amounts of logs. Reports can be configured on a FortiGate unit or a FortiAnalyzer unit. However, in this document only FortiOS reports are explained. FortiOS reports are the reports that are generated on the FortiGate unit. FortiAnalyzer reports are configured on a FortiAnalyzer unit and for information about those reports, see the [FortiAnalyzer Administration Guide](#).

Disk or memory logging must be enabled for reporting to be enabled. Local Reporting can then be enabled in *Log & Report > Log Setting*, in order to view and edit reports.

## What are FortiOS reports?

FortiOS reports are configured from logs stored on the FortiGate unit's hard drive. These reports, generated by the FortiGate unit itself, provide a central location for both configuring and generating reports. A default FortiOS report, called the FortiGate Security Feature Daily Activity Report, is available for you to modify to your requirements. The default report provides a way to quickly and easily set up your own report from within the web-based manager. The default FortiOS report is a report that compiles security feature activity from various security-related logs, such as virus and attack logs.

FortiOS reports consist of multiple parts, regardless of whether its the default FortiOS report or a report that you have configured from scratch, and these parts are configured separately and added to the layout. These parts of a FortiOS report are:

- charts (including datasets within the charts themselves)
- themes (including styles which are within the themes themselves)
- images
- layout

## The parts of a FortiOS report

Charts are used to display the log information in a clear and concise way using graphs and tables. Charts contain datasets, which are SQLite queries that help the FortiGate unit to add specific log information into the chart using the log information that is stored in the SQLite database on the local hard disk. If you want to configure a chart, you must configure the dataset first. Datasets are required for each chart, and if there is no dataset included in a chart, the chart will not be saved.

Themes provide a one-step style application for report layouts. Themes contain various styles, including styles for the table of contents, headings, headers and footers, as well as the margins of the report's pages. Themes are applied to layouts. The styles that are applied to themes are configured separately in the CLI.

You can easily upload your company or organization's logo to use within a report. By uploading your company or organization's logo and applying it to a report, you provide a personalized report that is recognizable as your company or organization's report. The image must be in JPEG, JPG or PNG format.

Layouts provide a way to incorporate the charts, images, and themes that are configured to create a formatted report. A layout is used as a template by the FortiGate unit to compile and then generate the report. The layout is also coded in the CLI.

## What you can do with the default FortiOS report

You can reset the reports you have configured, as well as the default FortiOS report you modified, to default settings. When you reset reports to default settings, any configured reports that you created from scratch are lost. The `execute report-config reset` command resets the reports to default settings. If you are going to reset the reports to their default settings, you should back up the current configuration file before doing so, in the event you want to revert back to the reports you previously created and/or modified.

The default FortiOS report can be modified so that it meets your requirements for a report. This default report is located in *Log & Report > Report > Local*. Select *Customize* to edit it.

The FortiOS default report contains several pages, which appear as stacked boxes in the editing interface. Each page contains one or multiple charts (depending on the configuration of that page in the interface), and each page in the finished report will contain information about the FortiGate unit at the top of each section.

You can select *Run Now* on the *Local* page to immediately create a report with the current layout and design. More complex reports may take longer to generate. After generating a report, you can view it by selecting it from the list below *Run Now*. Historical reports will be marked as 'Scheduled' if created automatically, or 'On Demand' if created by selecting *Run Now*.

## How to modify the default FortiOS report

The following is a sample modification of the default FortiOS report, which includes adding an image.

1. In *Log & Report > Report > Config*, modify the page by adding a new Chart, which will appear on its own page in the final report.
2. Add an information Text field below the chart.  
You should always save the changes you make by selecting *Save*; otherwise, the changes you just made will be lost.
3. Modify the header to add the company's image.  
The company's image will appear in all headers throughout the report. If you select *Save* now, it will appear on all the report's pages.
4. Add other charts to the list so they will appear within the report.  
Charts marked as 'FortiGate Security Feature Security Analysis Report' are autogenerated and take up an entire page or multiple pages on their own. All other charts take up half a page, so two consecutive charts will appear on the same page in the report.
5. Modify the report settings so that the report is generated every Monday at 6 pm, and is emailed to specific employees in the company.  
Reports can be sent to others after the report has been generated, if Messaging Servers are configured.
6. Test the report's modified settings, by selecting *Run Now* in the Config page; after it is generated, go to *Log & Report > Report > Local* and view the report.  
You can tell that it has been generated because the Bandwidth Usage page's charts will be populated, and the text added below each chart appears as well.

## How to create a FortiOS report

This creates a FortiOS report from within the CLI. This is not modifying a default report, rather, it is creating one from scratch. This can take quite a while since there is a lot of commands to use. This is a time-consuming activity, so it is recommended that you allow yourself plenty of time to configure a FortiOS report. To see some sample configuration, view ["Customizing FortiOS reports with CLI" on page 1976](#).

1. Log in to the CLI and, using the `config report style` command, configure the styles for the footer and header, page, cover page, charts, table of contents, and page headings.  
It is recommended that you outline what you will be doing first, before configuring a report from scratch. When configuring new charts, you must also configure datasets. Charts will not be saved if a dataset is not associated with the chart. When configuring datasets, you must know SQL language.
2. Configure the theme using the `config report theme` command.  
A theme applies the styles that you configured previously in step 1.
3. Configure the new datasets that you want to have for the new charts using the `config report dataset` command.  
A dataset contains the information the FortiGate unit needs to gather the information for a chart. The log database is an SQL database, and that is why the datasets must be written in SQL; specifically, the log database uses SQLite so you must make sure that the information

is correct in a dataset. If the information is not correct, the FortiGate unit will not gather the proper information for that chart.

4. Configure the new charts that you want and make sure to apply the correct dataset with the chart using the `config report chart` command.
5. Configure the report layout using the `config report layout` command.  
The layout puts all the pieces of the report together. The layout provides a template for the FortiGate unit to know how the pieces should be put together and where they need to be on the pages of the report. The layout also allows for specifying when the report will be generated, and what style will be applied.
6. Test the report by going back to the report layout and setting the time so that the report immediately generates; it will then appear in the list of reports in the web-based manager.

## Best Practices: Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- what FortiGate activities you want and/or need logged (for example, security features)
- the logging device best suited for your network structure
- if you want or require archiving of log files
- ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

1. Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.
2. Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPSec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPSec tunnel errors occur.
3. If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the IM usage dashboard widget or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
4. Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to

ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

# Logging and reporting for small networks

This section explains how to configure the FortiGate unit for logging and reporting in a small office or SOHO/SMB network. To properly configure this type of network, you will be modifying the default log settings, as well as the default FortiOS report.

The following procedures are examples and can be used to help you when configuring your own network's log topology. Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own network's log topology.

The following topics are included in this section:

- [Modifying default log device settings](#)
- [Configuring the backup solution](#)
- [Modifying the default FortiOS report](#)

## Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

### Modifying the FortiGate unit's system memory default settings

When the FortiGate unit's default log device is its system memory, the following is modified for a small network topology. The following is an example of how to modify these default settings.

#### To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
    set ips-archive disable
    set status enable
end
```

3. The following example command syntax modifies which FortiGate features that are enabled for logging:

```
config log memory filter
    set attack enable
    set forward-traffic enable
    set local-traffic enable
    set netscan enable
    set email-log-imap disable
    set multicast-traffic enable
    set scanerror enable
    set app-ctrl enable
end
```

## Modifying the FortiGate unit's hard disk default settings

When the FortiGate unit's default log device is its hard disk, you need to modify those settings to your network's logging needs so that you can effectively log what you want logged. The following is an example of how to modify these default settings.

### To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
    set ips-archive disable
    set status enable
    set max-log-file-size 1000
    set storage FLASH
    set log-quota 100
    set report-quota 100
    set sql-max-size 10000
    set sql-max-size-action overwrite
    set sql-oldest-entry 1024
    set rows-per-transaction 100
    set ms-per-transaction 6000
    config sql-logging
        set netscan disable
        set spam disable
    end
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log disk filter
    set discovery disable
    set email-log-imap disable
end
```

## Testing sending logs to the log device

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

## To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an attack detection message with level - warning
generating an application control IM message with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
generating netscan log messages with level - notice
generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
generating a NAC QUARANTINE message with level - information
generating a URL block message with level - warning
```

2. In the web-based manager, go to *Log & Report > Event Log > User*, and view the logs to see the recently generated test log messages.

You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2. If you have disabled certain logs that are logged to the SQL log database, the following will appear in red at the top of the Log Table: ‘Warning: SQL Logging is not enabled.’

## Configuring the backup solution

A backup solution provides a way to ensure logs are not lost. The following backup solution explains logging to a FortiCloud server and uploading logs to a FortiAnalyzer unit. With this backup solution, there can be three simultaneous storage locations for logs, the first being the FortiGate unit itself, the FortiAnalyzer unit and then the FortiCloud server.

### Configuring logging to a FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how to these settings are configured for a network’s log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can only be done in the CLI; however, for uploading of logs to a FortiAnalyzer unit, you can modify the upload time and interval settings from the web-based manager after you have configured it in the CLI.

### To configure logging to the FortiCloud server

1. Go to *System > Dashboard > Status* and click *Login* next to *FortiCloud* in the License Information widget.
2. Enter your username and password, and click OK.
3. The logs will automatically be uploaded to FortiCloud as long as you are logged in.
4. To configure the upload time and interval, go to *Log & Report > Log Config > Log Settings*.
5. Under the Logging and Archiving header, you can select your desired upload time.

If your logs do not appear to be reaching the FortiCloud server, go to *System > Config > FortiGuard* and see what the status of *FortiGuard Availability* is.

In this video, you'll be learning how to use FortiCloud to view log data and reports.

With FortiCloud you can easily store and access FortiGate logs and reports that can give you valuable insight into the health and security of your network.

## Configuring uploading logs to the FortiAnalyzer unit

The logs will be uploaded to the FortiAnalyzer unit at a scheduled time. The following is an example of how to upload logs to a FortiAnalyzer unit.

### To upload logs to a FortiAnalyzer unit

1. Go to *Log & Report > Log Config > Log Settings*.
2. In the *Logging and Archiving* section, select the check box beside *Send Logs to FortiAnalyzer/FortiManager*.
3. Select *FortiAnalyzer (Daily at 00:00)*.
4. Enter the FortiAnalyzer unit's IP address in the *IP Address* field.
5. To configure the daily upload time, log in to the CLI.
6. Enter the following to configure when the upload occurs, and the time when the unit uploads the logs:

```
config log fortianalyzer setting
    set upload-interval {daily | weekly | monthly}
    set upload-time <hh:mm>
end
```

7. To change the upload time, in the web-based manager, select *Change* beside the upload time period, and then make the changes in the Upload Schedule window. Select *OK*.

## Testing uploading logs to a FortiAnalyzer unit

You should test that the FortiGate unit can upload logs to the FortiAnalyzer unit, so that the settings are configured properly.

### To test the FortiAnalyzer upload settings

1. Go to *Log & Report > Log Config > Log Settings*.
2. In the *Logging and Archiving* section, under *Send Logs to FortiAnalyzer/FortiManager*, change the time to the current time by selecting *Change*.  
For example, the current time is 11:10 am, so *Change* now has the time 11:10.
3. Select *OK*.

The logs will be immediately sent to the FortiAnalyzer unit, and will be available to view from within the FortiAnalyzer's interface.

## Modifying the default FortiOS report

The default FortiOS report is provided to help you quickly and easily configure and generate a report. The following is an example of how to modify the default FortiOS report.

### To modify the default FortiOS report

1. In the web-based manager, go to *Log & Report > Report > Local*.
2. Select *Customize* to open the Report Editor.
3. Change the default Fortinet image to the new image: select the Fortinet image and right-click so that *Delete* icon appears, and then select *Delete*; drag the Image icon to the box where the Fortinet image was previous; choose or upload a new image and then select *OK*.
4. Return to *Log & Report > Report > Local*.
5. Under *Report Options*, set the Generate report schedule to *Daily* and set a Time for the report to be compiled every day.
6. Enable *Email Generated Reports*. You may have to configure an SMTP server to send the reports before this option can be enabled. The SMTP configuration can be found in *System > Config > Messaging Servers*.
7. Select *Apply* to save the changes.
8. Select *Run Now* to generate a new On Demand report based on your changes.
9. Select the report from the Historical Reports list to view it.

Running On Demand reports can be a good way to compare report modifications as you configure.

# Logging and reporting for large networks

This section explains how to configure the FortiGate unit for logging and reporting in a larger network, such as an enterprise network. To set up this type of network, you are modifying the default log settings, and you are also modifying the default report.

The following procedures are examples and can be used to help you when configuring your own network's log topology. Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own network's log topology.

The following topics are included in this section:

- [Modifying default log device settings](#)
- [Configuring the backup solution](#)
- [Modifying the default FortiOS report](#)

## Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled and well as logging to either the FortiGate unit's system memory or hard disk, depending on the model.

### Modifying multiple FortiGate units' system memory default settings

When the FortiGate unit's default log device is its system memory, you can modify it to fit your log network topology. In this topic, the following is an example of how you can modify these default settings.

#### To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
    set ips-archive disable
    set status enable
end
```

3. Enter the following command syntax to modify the FortiGate features that are enabled for logging:

```
config log memory filter
    set attack enable
    set forward-traffic enable
    set local-traffic enable
    set netscan enable
    set email-log-imap enable
    set multicast-traffic enable
    set scanerror enable
    set app-ctrl enable
end
```

4. Repeat steps 2 and 3 for the other FortiGate units.
5. Test the modified settings using the procedure [“To test sending logs to the log device” on page 1962](#).

## Modifying multiple FortiGate units' hard disk default log settings

You will have to modify each FortiGate unit's hard disk default log settings. The following is an example of how to modify these default settings.

### To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
    set ips-archive disable
    set status enable
    set max-log-file-size 1000
    set storage Internal
    set log-quota 100
    set report-quota 100
    set sql-max-size 10000
    set sql-max-size-action overwrite
    set sql-oldest-entry 1024
    set rows-per-transaction 100
    set ms-per-transaction 6000
    config sql-logging
        set netscan disable
        set spam disable
    end
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log disk filter
    set discovery disable
    set email-log-imap disable
end
```

4. Repeat the steps 2 to 4 for the other FortiGate units.
5. Test the modified settings using the procedure [“To test sending logs to the log device” on page 1962](#).

## Testing the modified log settings

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

### To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an attack detection message with level - warning
generating an application control IM message with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
